Application for authorisation in terms of the National Environmental Management Act, Act No. 107 of 1998, as amended and the Environmental Impact Assessment (EIA) Regulations, 2014, as amended (the Regulations)

PROJECT TITLE

Proposed construction of the Pofadder Wind Energy Facility 3 and Associated Infrastructure, near Pofadder in the Northern Cape Province.

Kindly note the following:

1. This form must always be used for applications that must be subjected to Basic Assessment or Scoping & Environmental Impact Reporting where this Department is the Competent Authority.
2. This form is current as of 01 September 2018. It is the responsibility of the Applicant / Environmental Assessment Practitioner (EAP) to ascertain whether subsequent versions of the form have been published or produced by the Competent Authority. The latest available Departmental templates are available at https://www.environment.gov.za/documents/forms.
3. A copy of this form containing original signatures must be appended to all Draft and Final Reports submitted to the department for consideration.
4. All documentation delivered to the physical address contained in this form must be delivered during the official Departmental Officer Hours which is visible on the Departmental gate.
5. All EIA related documents (includes application forms, reports or any EIA related submissions) that are faxed; emailed; delivered to Security or placed in the Departmental Tender Box will not be accepted, only hardcopy submissions are accepted.

Report Prepared by: Jonathan Aronson
Issue Date: 28/02/2022
Version No.: 1-1

POFADDER WIND ENERGY FACILITY 3 (PTY) LTD
POFADDER WEF 3
SCOPING REPORT

EXECUTIVE SUMMARY

Pofadder Wind Energy Facility 3 (Pty) Ltd is proposing the development of a commercial Wind Energy Facility (WEF) and associated infrastructure called Pofadder WEF 3 ("the project"). The site is located approximately 20 km Southeast of Pofadder within the Kai !Garib Local Municipality and the Z F Mgcawu District Municipality in the Northern Cape Province, South Africa.

Collisions with wind turbine blades are one of the leading causes of bat mortality globally (Cryan, 2011; O'Shea et al., 2016) and therefore specialist studies are required to assess potential impacts of such infrastructure on bats (MacEwan et al. 2020b, SANBI2020). This report presents a Bat (Chiroptera) Specialist Assessment for the Pofadder WEF 3, forming part of the Scoping phase for Environmental Authorisation of the project. The objectives of this assessment are to present the baseline ecological condition of the project for bats, and to use these characterisations to predict and assess the potential impact of Pofadder WEF 3 on bat species and their habitats as well as to provide actions to mitigate impacts if required.

The baseline was determined by using acoustic monitoring to record spatial-temporal bat activity patterns, and roost surveys to locate used or potentially used bat roosting sites. This assessment is based on the data collected between 29 June 2021 and 2 December 2021 (157 nights). Bat acoustic activity was sampled at five locations within the study area by recording bats at 50 m and 100 m at three locations, and at 10 m at two locations. The monitoring period spanned winter, spring, and the transition to summer when bat activity is typically lower in South Africa compared to summer and autumn when activity is higher (Taylor et al. 2013). Therefore, this assessment is based on the expected lower magnitude of bat activity meaning that collision risk could be higher than that presented in this report. Collision risk based on a full annual cycle of bat activity will be determined upon completion of the 12 month of bat monitoring and assessed in the Final ESIA.

Based on current taxonomic information and bat occurrence data, eight bat species could occur at the project, four of which have been confirmed based on the acoustic data recorded thus far. No Threatened species were recorded or expected to occur on site but based on habitat suitability modelling (Monadjem et al. 2010), it is possible that the distribution of the nationally Near Threatened Angolan Wing-gland Bat (*Cistugo seabrae*) may overlap with the project although the project is at the southern extreme extent of its distribution. Over the 157 nights of sampling, 1,546 bat passes were recorded and activity was generally low (typical for the sampling period), but activity peaked to relatively higher levels on specific nights although this occurred rarely. Eighty six percent of total activity was attributed to Egyptian free-tailed bat, while 13 % was attributed to Roberts's Flat-headed Bat. Cape serotine and Long-tailed serotine were seldomly recorded. Bat activity was highest at 100 m across the study area. There were no major differences between bat activity at 10 m compared to 50 m, both of which were notably lower compared to activity at 100 m. Based on the magnitude of bat activity recorded, risk to bats would be medium at approximately 100 m and low closer towards ground level.

To assist in avoiding impacts to bats, buffers have been placed around key habitat features as per best practice resulting in the identification of several no-go areas for turbine placement. Four turbines in the proposed layout are within no-go areas and must be relocated: WTG63, WTG75, WTG77 and WTG79. Once operational, bat fatality monitoring must be undertaken to search for bat carcasses beneath wind turbines to measure the observed impact of the WEF on bats for a minimum of two years (Aronson et al. 2020). Mitigation measures that are known to reduce bat fatality if needed based on the fatality monitoring results include curtailment and acoustic deterrents (Arnett et al. 2013, Romano et al. 2019, Weaver et al. 2020). These techniques must be used if post-construction fatality monitoring indicates that species fatality thresholds have been exceeded (MacEwan et al. 2018) to reduce the impacts to bats to within acceptable limits of change and prevent declines in the impacted bat population. If these are adhered to, the Pofadder WEF 3 can be authorized without unacceptable levels of impacts to bats but pending the outcome of the remainder of the pre-construction bat monitoring which would provide a greater understanding of risk. These additional monitoring data will be assessed as part of the final ESIA and the impact assessment updated accordingly.

NATIONAL ENVIRONMENTAL MANAGEMENT ACT, 1998 (ACT NO. 107 OF 1998) AND ENVIRONMENTAL IMPACT REGULATIONS, 2014 (AS AMENDED) - REQUIREMENTS FOR SPECIALIST REPORTS (APPENDIX 6)

Regulation GNR 326 of 4 December 2014, as amended 7 April 2017, Appendix 6	**Section of Report**
1. (1) A specialist report prepared in terms of these Regulations must contain- a) details of- i. the specialist who prepared the report; and ii. the expertise of that specialist to compile a specialist report including a curriculum vitae;	Section 1.3 Appendix 2
b) a declaration that the specialist is independent in a form as may be specified by the competent authority;	pages 4, 5 and 6
c) an indication of the scope of, and the purpose for which, the report was prepared;	Section 1.1
(cA) an indication of the quality and age of base data used for the specialist report;	Section 1.4
(cB) a description of existing impacts on the site, cumulative impacts of the proposed development and levels of acceptable change;	Section 5, Page 12, Section 6.2.4
d) the date and season of the site investigation and the relevance of the season to the outcome of the assessment;	Section 1.4
e) a description of the methodology adopted in preparing the report or carrying out the specialised process inclusive of equipment and modelling used;	Section 1.4
f) details of an assessment of the specific identified sensitivity of the site related to the proposed activity or activities and its associated structures and infrastructure, inclusive of a site plan identifying site alternatives;	Section 6
g) an identification of any areas to be avoided, including buffers;	page 12
h) a map superimposing the activity including the associated structures and infrastructure on the environmental sensitivities of the site including areas to be avoided, including buffers;	Appendix 1 (Figure 6)
i) a description of any assumptions made and any uncertainties or gaps in knowledge;	Section 2
j) a description of the findings and potential implications of such findings on the impact of the proposed activity, (including identified alternatives on the environment) or activities;	Section 6.1

Regulation GNR 326 of 4 December 2014, as amended 7 April 2017, Appendix 6	**Section of Report**
k) any mitigation measures for inclusion in the EMPr;	Section 7
l) any conditions for inclusion in the environmental authorisation;	Section 7
m) any monitoring requirements for inclusion in the EMPr or environmental authorisation;	Section 7
n) a reasoned opinion- i. (as to) whether the proposed activity, activities or portions thereof should be authorised; (iA) regarding the acceptability of the proposed activity or activities; and ii. if the opinion is that the proposed activity, activities or portions thereof should be authorised, any avoidance, management and mitigation measures that should be included in the EMPr, and where applicable, the closure plan;	Section 8
o) a description of any consultation process that was undertaken during the course of preparing the specialist report;	NA
p) a summary and copies of any comments received during any consultation process and where applicable all responses thereto; and	NA
q) any other information requested by the competent authority.	NA
2) Where a government notice *gazetted* by the Minister provides for any protocol or minimum information requirement to be applied to a specialist report, the requirements as indicated in such notice will apply.	Appendix 3: Site Verification Report

POFADDER WIND ENERGY FACILITY 3 (PTY) LTD
POFADDER WEF 3
SCOPING REPORT

1. INTRODUCTION

The applicant Pofadder Wind Energy Facility 3 (Pty) Ltd is proposing the development of a commercial Wind Energy Facility (WEF) and associated infrastructure called Pofadder WEF 3 ("the project"). The site is located approximately 20 km Southeast of Pofadder within the Kai !Garib Local Municipality and the Z F Mgcawu District Municipality in the Northern Cape Province, South Africa.

A preferred project site with an extent of approx. 3000ha has been identified as a technically suitable area for the development of the Pofadder WEF 3, which will comprise of up to 30 turbines with a combined contracted capacity of up to 200MW. The project site is located on the following properties:

- The Farm Ganna-Poort 202;
- The Farm Lovedale 201; and
- Portion 3 of the Farm Sand Gat 150.

Two additional WEF's are concurrently being considered on the properties and are assessed by way of separate impact assessment processes contained in the 2014 Environmental Impact Assessment Regulations (GN No. R982, as amended) for listed activities contained Listing Notices 1, 2 and 3 (GN R983, R984 and R985, as amended). These projects are known as Pofadder Wind Energy Facility 2 and Pofadder Wind Energy Facility 3.

1.1 Scope and Objectives

This report presents a Bat (Chiroptera) Specialist Assessment for the Pofadder WEF 3. Collisions with wind turbine blades are one of the leading causes of bat mortality globally (Cryan, 2011; O'Shea et al., 2016) and therefore specialist studies are required to assess potential impacts of such infrastructure on bats (MacEwan et al. 2020b, SANBI2020). This assessment forms part of the Scoping phase for Environmental Authorisation of the project. The specialist assessment presented here is therefore preliminary and will be updated with additional data being collected as part of the baseline 12-month monitoring program to assess risk to bats.

The objectives of this assessment are to present the baseline ecological condition of the project for bats, and to use these characterisations to predict and assess the potential impact of Pofadder WEF 3 on bat species and their habitats as well as to provide actions to mitigate impacts if required.

1.2 Terms of Reference

The following terms of reference guided the compilation of this scoping report:

- Describe the baseline environment of the project and its sensitivity with regard to bats (Chiroptera)

- Identify the nature of potential impacts of the proposed project on bats during construction, operation and decommissioning;
- Conduct a significance rating and impact assessment of identified impacts;
- Identify information gaps and limitations; and
- Identify potential mitigation or enhancement measures to minimise impacts to bats.

1.3 Specialist Credentials

The bat pre-construction monitoring and impact assessment is being undertaken by Jonathan Aronson, who has 13 years of experience working on wildlife and wind energy impacts. A CV outlining this experience is available in Appendix 2.

1.4 Assessment Methodology

The Project Area of Influence (PAOI) was defined as the project boundary plus a 10 km buffer given that bats are volant mammals (Scottish Natural Heritage 2019). This area was studied at a desktop level to determine which bat species (i.e., impact receptors) are likely to occur at the project, to provide information on their natural history and conservation status, and to contextualise the project site within the larger social-ecological environment with respect to bats. Bats were also studied through field surveys in the preferred project site encompassing all three Pofadder WEFs ("project boundary"), covering an area of approximately 24,000 hectares (Figure 1, Appendix 1). The field data from this area, as well as the desktop information from the PAOI, was used to assess impacts for each Pofadder WEF individually.

Bat acoustic activity was sampled at five locations within the project boundary with Wildlife Acoustics, Inc. SM4 bat detectors (Figure 1 and Table 1). Since a preliminary turbine layout was available, the study design was focused on surveying areas within the project boundary where turbines were likely to be installed. In addition, the study design prioritised collecting bat activity at height because three 100 m meteorological towers are present. At two locations (PO1 and PO2), SMM-U2 microphones were fixed to the top of a 10 m aluminium mast. At three locations (PO3, PO4, and PO5), microphones were attached to a meteorological tower at 50 m and 100 m respectively. Sampling took place nightly from sunset to sunrise, commencing 29 June 2021 and will continue for 12 months.

This report is based on data collected between 29 June 2021 and 2 December 2021 (157 nights). The monitoring period therefore spans winter, spring, and the transition to summer. Typically in South Africa, bat activity is lower during this period compared to summer and autumn when activity is higher (Taylor et al. 2013). Therefore, this assessment is based on the expected lower magnitude of bat activity meaning that collision risk could be higher than that presented in this report. Collision risk based on a full annual cycle of bat activity will be determined upon completion of the 12 month of bat monitoring and assessed in the Final ESIA.

Acoustic data were retrieved from each bat detector (on 25 August 2021 and 2 December 2021) and analysed using Kaleidoscope® Pro (Version 5.4.2, Wildlife Acoustics, Inc.). Bats were automatically identified using the embedded "Bats of South Africa Version 5.4.0" reference library and verified by inspecting echolocation files. The number of acoustic files recorded was used as a measure to quantify bat activity.

To locate features on site where bats maybe/are roosting, surveys were undertaken which first entailed discussions with landowners to locate any known roosts, or potential roosts with evidence of bats. Secondly, eight buildings at one of the farmsteads within the project were systematically surveyed on 26 August 2021 (Figure 1). The surveys aimed to directly observe roosting bats, locate evidence of roosting bats (e.g., insect remains, fur-oil-stained exit and entry points, guano/droppings), and assess the potential for each building to support bats. Additional roost surveys will take place at other locations during the remainder of the monitoring.

Table 1: Summary of the Bat Acoustic Monitoring Sampling Locations and Effort

Bat Detector	Coordinates	# Sample Nights	Vegetation Type	Altitude (m)	Habitat Features
PO1	19.74°E 29.37°S	128	Bushmanland Arid Grassland	997	1.2 km/205° from river, 1.3 km/80° from depression wetland, 1.9 km/312° from farm dam and trees
PO2	19.66°E 29.32°S	96	Bushmanland Arid Grassland	1,048	767 m/120° from depression wetland, 1.2 km/94° from depression wetland, 1.7 km/267° from farm dam, buildings, and trees
PO3	19.67°E 29.28°S	60	Bushmanland Inselberg Shrubland	1,005 (+ 50 m)	1.7 km/265° from farm dam, 2.5 km/265° from farmstead, 3.7 km/88° from farmstead, ridgeline (east-west)
		157		1,005 (+ 100 m)	
PO4	19.75°E 29.29°S	60	Bushmanland Basin Shrubland	1,014 (+ 50 m)	650 m/302° from farm dam, buildings, and trees, 540 m/145° from Karoep river
		60		1,014 (+ 100 m)	
PO5	19.79°E 29.35°S	60	Bushmanland Arid Grassland	1,002 (+ 50 m)	1 km /202° from depression wetland, 2 km m/54° from farm dam, buildings, and trees, 2 km/288° from farm dam and trees
		144		1,002 (+ 100 m)	

2. ASSUMPTIONS AND LIMITATIONS

The core techniques used to assess bat activity in this study are acoustic monitoring and roost surveys both of which have several limitations which will influence the findings and recommendations of this study.

Acoustic monitoring allows for rapid, passive collection of a large volume of bat activity data which can help identify the bat species present within a particular location and their associated relative spatio-temporal activity patterns. In the context of wildlife and wind farm interactions, acoustic monitoring is therefore a useful technique however, there are several constraints that must be acknowledged.

These are discussed in detail by Voigt et al. (2021), Adams et al. (2012), and Kunz et al. (2007) and fundamentally, include that acoustic monitoring cannot provide an indication of bat abundance or population size at a site. In addition, population demographics such as age and sex of bats cannot be determined from echolocation calls. Due to the large volume of data collected by bat detectors it is impractical and prohibitively time-consuming to inspect each file recorded by a bat detector for echolocation calls and to identify the associated bat species. Specialised statistical software uses bat call reference libraries to automate the identification process but developing such libraries is challenging given the variation individual species display in their echolocation call structure and overlap in these structures between species. This study used the Wildlife Acoustics library "Bats of South Africa Version 5.4.0", but this excludes reference calls for most South African species thus these may have been overlooked. Lastly, bat activity is notably variable in response to several factors such as land use change, climactic variability, variations in prey abundance and meteorological conditions which can vary over different time scales. Since this study is limited to 12 months, the baseline conditions presented here may not be representative of activity over longer time frames meaning risk may be misinterpreted.

The major limitation with roost surveys is finding roosting bats. Bats use a diversity of roosting sites including trees, buildings, crevices, and underground sites (caves and mines). The presence of these features at a site can help to target roost searches but evidence of bats may not always be apparent even if bats are present. Importantly, the absence of bat evidence in these situations does not equate to evidence of bat absence (Collins, 2006). Thus, this study uses a precautionary approach and will apply buffers to roosts (largely buildings and rocky crevices) even if bats were not located given their potential role in supporting roosting bats.

3. TECHNICAL DESCRIPTION

3.1 Project Location

The project site comprises the following farm portions:

- The Farm Ganna-Poort 202;
- The Farm Lovedale 201; and
- Portion 3 of the Farm Sand Gat 150.

3.2 Project Description

The Pofadder WEF 3 project site is proposed to accommodate the following infrastructure, which will enable the wind farm to supply a contracted capacity of up to 200 MW:

- Up to 30 wind turbines with a maximum hub height of up to 200 m;
- A transformer at the base of each turbine;
- Concrete turbine foundations and turbine hardstands;
- Temporary laydown areas which will accommodate the boom erection, storage and assembly area;
- Cabling between the turbines, to be laid underground where practical;
- An on-site substation of up to 1.25 ha in extent to facilitate the connection between the wind farm and the electricity grid;
- An internal overhead 132 kV power line, with a servitude of 32 m, to connect the wind farm to the collector substation (this will be assessed in a separate Grid BAR);
- Access roads to the site and between project components inclusive of stormwater infrastructure with a width of up to 12m;;

- A temporary concrete batching plant; and
- Operation and Maintenance buildings including a gate house, security building, control centre, offices, warehouses, a workshop and visitors centre.

In order to evacuate the energy generated by the WEF's to supplement the national grid, Pofadder Grid (Pty) Ltd is proposing to develop a ~58 km (132/400 kV) high voltage overhead transmission powerline to connect the three proposed wind farms to the new planned Eskom Karana Substation. Application for a corridor in which to situate the gridline is the subject of a separate EA application (Pofadder Grid for the Pofadder Wind Energy Facilities). The EA applications for the three wind farm projects and gridline are being undertaken in parallel as they are co-dependent, i.e. one will not be developed without the other.

4. LEGAL REQUIREMENTS AND GUIDELINES

There are various international, regional and local legislation, policies, regulations, guidelines, conventions, and treaties in place for the protection of biodiversity, under which bats would also be protected. These include:

- Convention on the Conservation of Migratory Species of Wild Animals (1979)
- Convention on Biological Diversity (1993)
- Constitution of the Republic of South Africa, 1996 (Act No. 108 of 1996)
- National Environmental Management Act, 1998 (NEMA, Act No. 107 of 1998)
- National Environmental Management: Biodiversity Act, 2004 (Act No. 10 of 2004)
- Northern Cape Nature Conservation Act, 2009 (Act No. 9 of 2009)
- The Equator Principles (2013)
- The Red List of Mammals of South Africa, Swaziland and Lesotho (2016)
- National Biodiversity Strategy and Action Plan (2005)
- South African Good Practise Guidelines for Surveying Bats in Wind Energy Facility Developments – Pre-Construction (2020)
- South African Good Practise Guidelines for Operational Monitoring for Bats at Wind Energy Facilities (2020)

5. DESCRIPTION OF THE RECEIVING ENVIRONMENT

The Project Area of Influence (PAOI) is situated in the arid Nama Karoo Biome and the landscape is characterised by open, relatively flat, and sparsely vegetated plains with mountainous terrain (inselbergs and koppies) in the north and northwest (Figure 1). The vegetation is dominated by Bushmanland Arid Grassland comprising low growing shrubs and bunch grasses at low density. Bushmanland Basin Shrubland and Bushmanland Inselberg Shrubland bisects the middle of the PAOI, and Eastern Gariep Rocky Desert vegetation occurs in the north. All of the vegetation types in the PAOI are classified as least concern (SANBI 2018). The vegetation structure has limited heterogeneity since grasses and shrubs dominate the landscape. However, the vegetation is more structurally complex in association with aquatic resources (rivers, drainage areas) and in isolated areas (e.g., at farmsteads and livestock watering points) where trees are present.

The climate in the PAOI is arid, with low, unreliable rain which falls mostly in late summer and early autumn, peaking in March, and droughts can occur, sometimes for prolonged periods (Mucina and Rutherford 2006). When rainfall is adequate annual herbs proliferate which tends to increase insect activity. These pulses could also result in periods of increased bat activity. Stock grazing is the primary land use and infrastructure within the project boundary is limited primarily to small farmsteads, other isolated buildings and ruins, farm roads, fences, farm dams, water pumps and livestock watering points.

Critical Biodiversity Areas (CBA2, Expert identified Important Terrestrial Habitat) are located in the northwest of the project boundary while Ecological Support Areas (ESA_T, Terrestrial Migration Corridors) cross the south and northwest of the project boundary (NCDENC 2010). The PAOI falls within a National Protected Areas Expansion Strategy (NPAES) Focus area (Kamiesberg Bushmanland Augrabies), areas targeted for protected area expansion for improved ecosystem representation, ecological sustainability and resilience to climate change (DEA 2016). The closest protected area to the PAOI is the Gamsberg Nature Reserve, located approximately 36 km west.

Bat roosting sites in the PAOI are relatively limited and unlikely to support large congregations of bats. The closest known major bat roosts are approximately 120 km northeast of the PAOI. Rocky outcrops are present primarily in the north and northwest and these geological features may provide roosting spaces for species such as Roberts's flat-headed bat, Egyptian free-tailed bat and Long-tailed serotine that roost in rocky crevices (Monadjem et al. 2018). The Long-tailed serotine roosts in small groups of a few individuals while Roberts's Flat-headed Bat tends to roost communally in small groups of tens of individuals (Jacobs and Fenton 2002). Egyptian free-tailed bats can roost in groups of tens to a few hundred individuals (Herselman and Norton 1985). Bats are also likely to roost in buildings associated with farmsteads within and bordering the project especially Cape Serotine and Egyptian Free-tailed Bat (Monadjem et al. 2018). Trees growing at these farmsteads, and in limited places elsewhere on site usually at livestock water points, could also provide roosting spaces for bats although the extent of this is likely limited since these trees are typically not large and day-time temperatures may be too hot (Monadjem et al. 2018). The building inspections on site did not reveal any evidence of roosting bats.

Sensitive features in the PAOI at which bat foraging activity may be concentrated include farmsteads, farm dams, the livestock water points, rocky outcrops, and along drainage networks/riparian areas. The presence of water, vegetation and lighting at these features could promote insect activity and hence attract foraging bats. For example, Long-tailed serotine have been captured foraging for flies at a livestock kraal (Shortridge 1942). Activity could also be concentrated along the non-perennial Karoep and Soutputs se Laagte rivers which flow through the northeast and south of the project respectively.

Based on current taxonomic information and bat occurrence data, eight bat species could occur at the project, four of which have been confirmed based on the acoustic data recorded thus far (Table 2). No Threatened species were recorded or expected to occur on site but based on habitat suitability modelling (Monadjem et al. 2010), it is possible that the distribution of the nationally Near Threatened Angolan Wing-gland Bat (*Cistugo seabrae*) may overlap with the project but there is little information on the natural history of this species (Jacobs et al. 2016). It is endemic to the west coast of southern Africa from northern South Africa to southern Angola, and the PAOI is located at the extreme southern edge of its distribution (Figure 2). The closest known localities of this species to the PAOI are between 85 km and 100 km north of the project near the Orange River (ACR 2020). This species is currently considered to be at low risk of wind energy impacts (MacEwan et al. 2020b).

Table 2: Bat Species Potentially Occurring at the Pofadder WEFs

Family	Common Name	*Species Name*	Conservation Status		WEF Risk$^{\delta}$	Habitat Requirements*	Prob. of Occurrence	Rationale
			IUCN†	RSA*				
Miniopteridae	Natal Long-fingered Bat	*Miniopterus natalensis*	LC/ Unknown	LC	High	Temperate or subtropical species. Primarily in savannas and grasslands. Roosts in caves, mines, and road culverts. Clutter-edge forager.	Low	Lack of suitable roosts (cave-dependent).
Vespertilionidae	Cape Serotine	*Laephotis capensis*	LC/ Stable	LC	High	Arid semi-desert, montane grassland, forests, savanna and shrubland. Roosts in vegetation and human-made structures. Clutter-edge forager.	**Confirmed**	Echolocation calls recorded.
Molossidae	Egyptian Free-tailed Bat	*Tadarida aegyptiaca*	LC/ Unknown	LC	High	Desert, semi-arid scrub, savanna, grassland, and agricultural land. Roosts in rocky crevices, caves, vegetation, and human-made structures. Open-air forager.	**Confirmed**	Echolocation calls recorded Suitable habitat and roosts.
Molossidae	Roberts's Flat-headed Bat	*Sauromys petrophilus*	LC/ Stable	LC	High	Wet and dry woodlands, shrublands and Acacia-wooded grasslands always in areas with rocky outcrops and hills. Roosts in narrow rock crevices and fissures. Open-air forager.	**Confirmed**	Echolocation calls recorded Suitable habitat.
Vespertilionidae	Long-tailed Serotine	*Eptesicus hottentotus*	LC/ Unknown	LC	Medium	Montane grasslands, marshland and well-wooded riverbanks, mountainous terrain near water. Roosts in caves, mines, and rocky crevices. Clutter-edge forager.	**Confirmed**	Echolocation calls recorded. Suitable roosts.
Cistugidae	Angolan Wing-gland Bat	*Cistugo seabrae*	LC/ Unknown	NT	Low	Limited knowledge of habitat and ecology. All records are in arid areas with mean annual rainfall < 100 mm. Previously captured in riverine vegetation along dry riverbeds and close to open water. Clutter-edge forager.	Low	Edge of range (Figure 2)
Nycteridae	Egyptian Slit-faced Bat	*Nycteris thebaica*	LC/ Unknown	LC	Low	Savannah, desert, arid rocky areas, and riparian strips. Gregarious and roosts in caves but also in mine adits, Aardvark holes, rock crevices, road culverts, roofs, and hollow trees. Clutter forager.	High	Common throughout range. Closest record 38 km north of PAOI (ACR 2020).
Rhinolophidae	Damara Horseshoe Bat	*Rhinolophus damarensis*	LC/ Unknown	LC	Low	Arid savannah and shrubland habitats within the Nama-Karoo Biome. Roosts in caves and mine adits. Clutter forager. Little is known about abundance or population trends of this species.	Medium	Suitable habitat but no suitable roosts. Closest record 64 km west of PAOI (ACR 2020).

LC = Least Concern; NT = Near Threatened

6. SPECIALIST FINDINGS / IDENTIFICATION AND ASSESSMENT OF IMPACTS

6.1 Summary of Pre-Construction Bat Monitoring

Over the 157 nights of sampling, 1,546 bat passes were recorded from four species. Eighty-six percent of total activity was attributed to Egyptian free-tailed bat, while 13 % was attributed to Roberts's Flat-headed Bat. Cape serotine and Long-tailed serotine were seldomly recorded. Bat activity was highest at PO3_100 and PO5_100 showing that the majority of activity was recorded at 100 m across the study area (Figure 3). There were no major differences between bat activity at 10 m compared to 50 m, both of which were notably lower compared to activity at 100 m (Table 3).

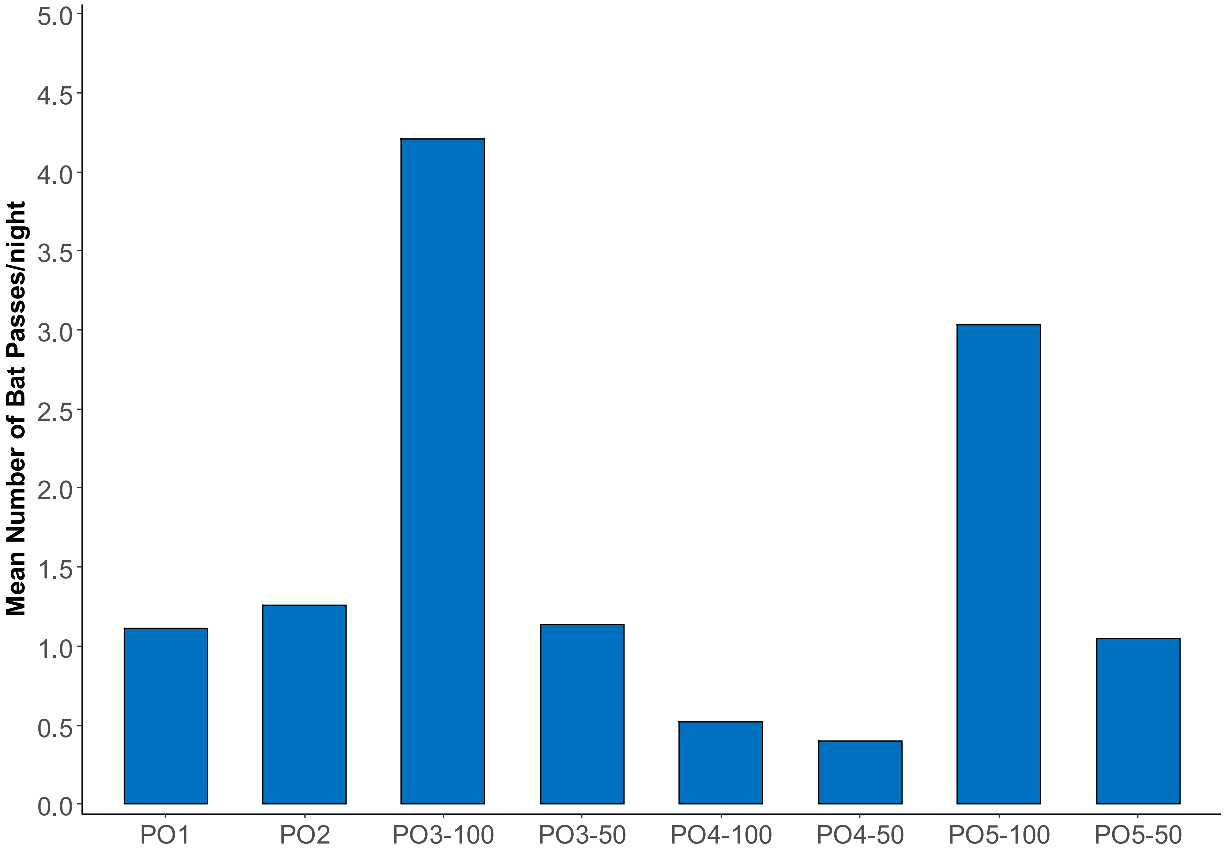

Figure 3: Bar chart showing mean bat activity recorded at each monitoring location.

As is typical, bat activity was lowest during winter (June through August), increasing in spring. In winter, approximately half of all sample nights had no bat activity in contrast to spring in which only a quarter of nights had no bat activity showing that bats tended to be more active in spring. Bat activity was highest in September (Figure 4) but this is largely attributed to bat activity on 10 September 2021 when 399 bat passes were recorded, accounting for 60 % of activity recorded during this month alone, and 25 % of activity across the 157 night study period. Bats can rapidly and opportunisitcally alter their activity patterns in response to periods of favourable climatic conditions, as well as track prey abundance (Paige 1995, McCracken et al. 2012, Barros et al. 2021). This increased activity was observed at both PO3 and PO5 (Figure 1) suggesting that conditions may have been conducive for higher activity across the study area.

During winter, bat activity was highest between 19:00 and 01:00 but there was little difference between each time period, with relatively constant activity throughout the night. Similarly, during spring, bat activity was highest between 19:00 and 03:00, with a peak from 00:00 to 02:00 before declining for the remainder of the night (Figure 5).

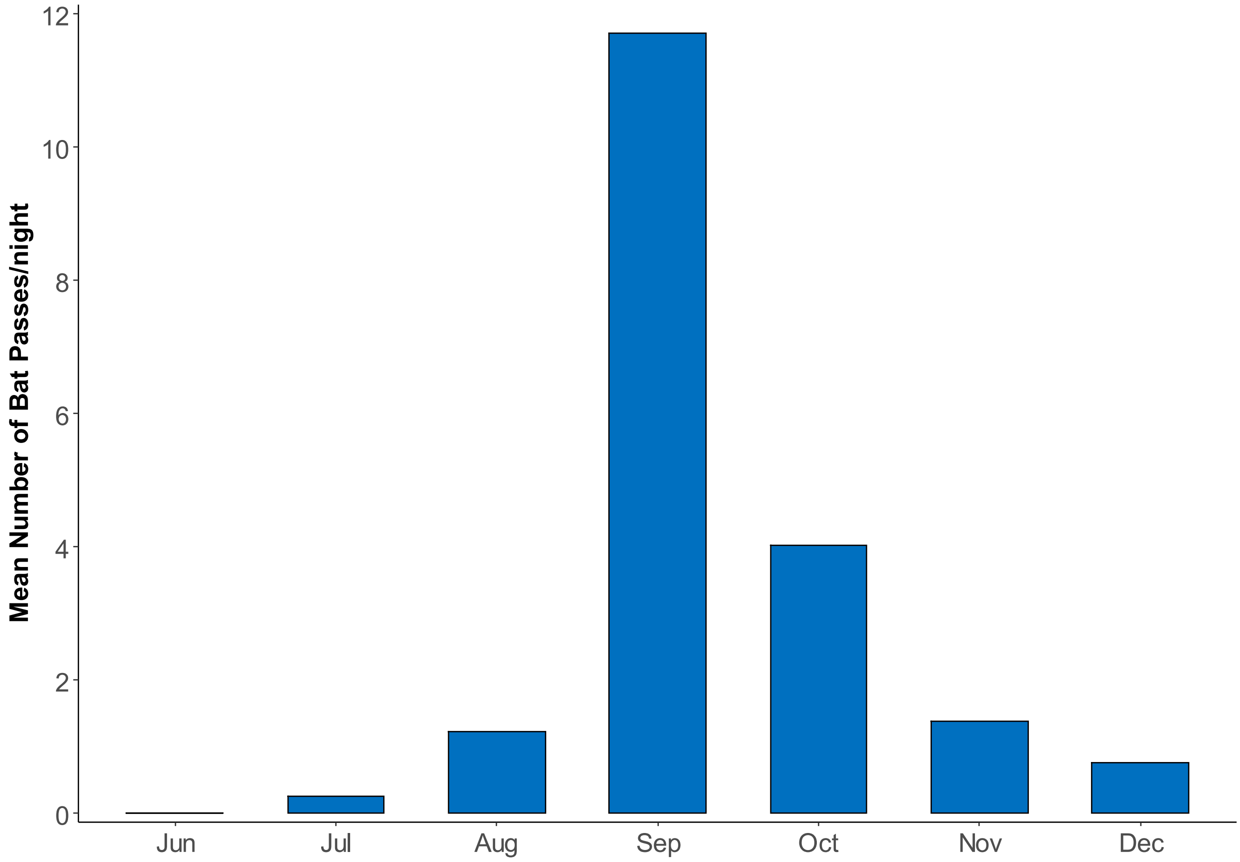

Figure 4: Mean number of bat passes/night across each sampling month.

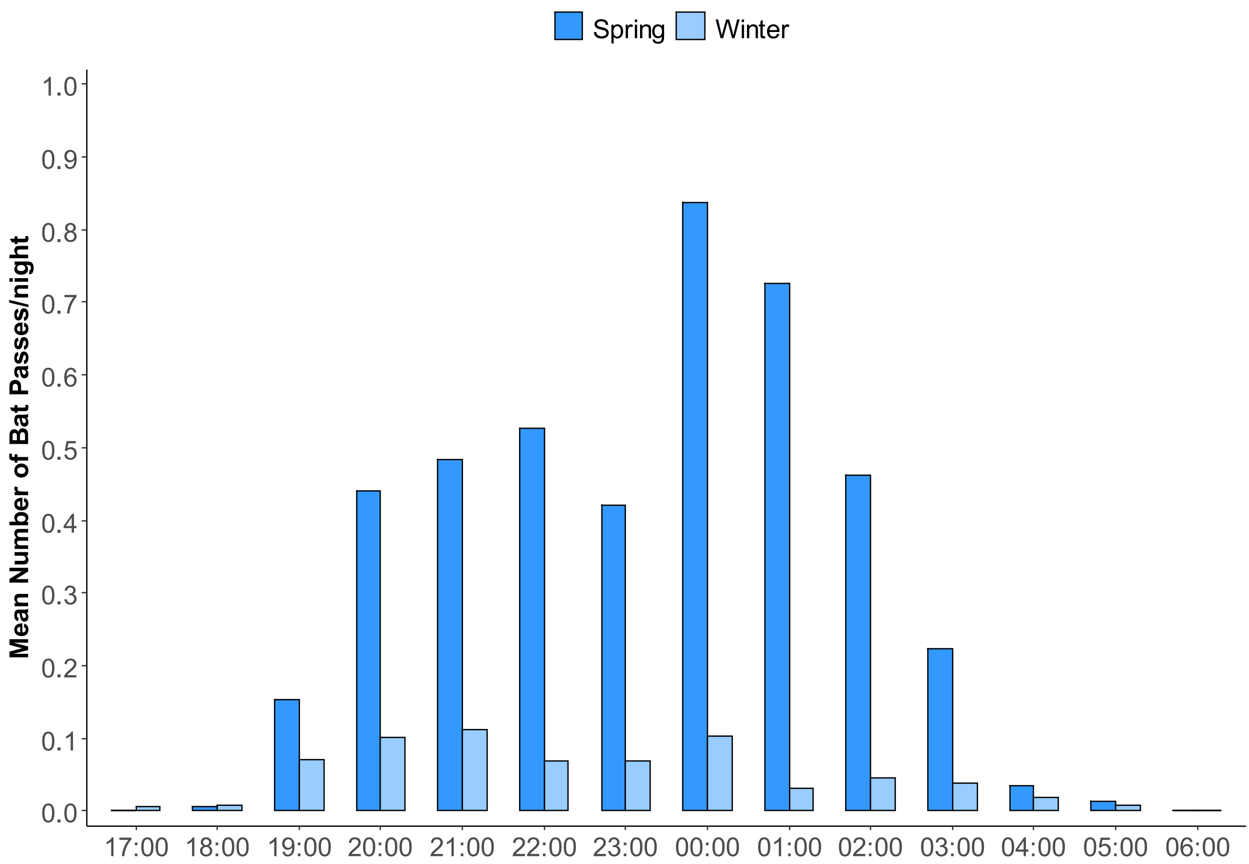

Figure 5: Mean number of bat passes per hour across nightly time periods. 17:00 represents bat activity between 17:00 and 18:00 etc.

Based on the preliminary data available at this stage of the project, activity of bats is dominated by high flying bat species - Roberts's Flat-headed Bat and Egyptian free-tailed bat. Both species are open-air foragers based on their morphology and echolocation (Norberg and Rayner 1987) which means they tend to forage high in the air. However, both will forage at ground level (e.g. Shortridge 1942) and were recorded at PO1 and PO2 at which bats are being sampled at approximately 10 m. For Egyptian free-tailed bats habitat does not generally influence its activity (Monadjem et al. 2020). Both species are classified as high risk to wind energy because of their foraging ecology however, based on best practice guidance and the acoustic monitoring results (MacEwan et al. 2020a, MacEwan et al. 2020b), risk to bats would be medium at approximately 100 m and low closer towards ground level (Table 3) but this will vary during the annual cycle of activity (i.e. risk may be higher in summer and/or autumn).

Table 3: Acoustic Monitoring Based Risk Profile for the Pofadder WEF 3

Height	Number of monitoring locations	Mean passes/night	Median passes/night	Median passes/hour	Risk Level
10 m	2	1.2	0.0	0.0	Low
50 m	3	0.9	0.0	0.0	Low
100 m	3	3.1	1.0	0.1	Medium

Additional data from the remaining monitoring will assist in determining risk during summer and autumn but for the period reported on here, the magnitude of activity suggests impacts to bats at Pofadder WEF 3 would not be beyond limits of acceptable change. However, pre-construction bat activity patterns do not always correlate with observed post-construction impacts (Hein et al. 2013, Lintott et al. 2016, Solick et al. 2020) and assessing risks to bats is challenging especially given the limited understanding of impacts to bats at operating wind farms in South Africa. Given this uncertainty, to assist in avoiding impacts to bats, buffers have been placed around key habitat features as per best practice (Figure 6, Appendix 1). Rivers, livestock water points, wetlands, farms dams, buildings and rocky outcrops have been buffered by 200 m. Small streams and drainage lines have been buffered by 50 m. All buffers are to blade tip. Four turbines in the proposed layout are within no-go areas and must be relocated: WTG63, WTG75, WTG77 and WTG79.

Once operational, bat fatality monitoring must be undertaken to search for bat carcasses beneath wind turbines to measure the observed impact of the WEF on bats for a minimum of two years (Aronson et al. 2020). Additional mitigation measures that are known to reduce bat fatality if needed based on the fatality monitoring results include curtailment and/or acoustic deterrents (Arnett et al. 2013, Romano et al. 2019, Weaver et al. 2020). These techniques must be used if post-construction fatality monitoring indicates that species fatality thresholds have been exceeded (MacEwan et al. 2018) to maintain the impacts to bats within acceptable limits of change and prevent declines in the impacted bat population.

According to the threshold guidance (MacEwan et al. 2018), the bias-adjusted threshold fatality value is 71 individuals per least concern bat species per annum based on an area of influence of 3,550 hectares for Pofadder WEF 3. Should this be exceeded, curtailment and/or acoustic deterrents must be used to reduce fatality levels to below the threshold. Although predicated to have low probability of occurrence (Figure 2), one fatality of Angolan Wing-gland Bat (*Cistugo seabrae*) would trigger the need for mitigation because this species is nationally Near Threatened (Table 2).

6.2 Identification and Assessment of Impacts

In preparing this impact assessment, the unit of analysis is the local bat community and their associated habitats within the PAOI. As such, impacts are not assessed relative to individual bats.

6.2.1 Construction Phase

Both indirect and direct impacts can occur during the construction phase. Indirect impacts include the removal of vegetation which can reduce foraging opportunities and alter commuting spaces for bats. Noise and dust generated through construction activities can also disturb bats. Construction activities near bat roosting spaces can indirectly impact bats, potentially resulting in roost abandonment. Direct impacts can occur if bat roosting spaces are destroyed. In addition, the installation of new infrastructure in the landscape (e.g., buildings, turbines, road culverts) can inadvertently provide new roosting spaces for some bat species, attracting them to areas with wind turbines and potentially increasing the likelihood of collisions.

ENVIRONMENTAL PARAMETER	ISSUE / IMPACT / ENVIRONMENTAL EFFECT/ NATURE	ENVIRONMENTAL SIGNIFICANCE BEFORE MITIGATION									RECOMMENDED MITIGATION MEASURES	ENVIRONMENTAL SIGNIFICANCE AFTER MITIGATION								
		E	P	R	L	D	I / M	TOTAL	STATUS (+ OR -)	S		E	P	R	L	D	I / M	TOTAL	STATUS (+ OR -)	S
Construction Phase																				
Bat habitat features (foraging/commuting habitat)	Vegetation clearing for access roads, turbines and their service areas and other infrastructure, as well as noise and dust generated during the construction phase, will indirectly impact bats by removing habitat used for foraging/commuting and through disturbance.	2	2	1	2	2	2	18	-	Low	Minimise clearing of vegetation, rehabilitate all areas disturbed during construction (including aquatic habitat), no placement of turbines within no-go areas, avoid construction activities at night.	1	1	1	2	1	1	6	-	Low
Bat habitat features (roost habitats)	Construction of WEF infrastructure could result in destruction (direct impact) of bat roosts (trees, rock crevices) and disturbance (indirect impact) of bat roosts (trees, buildings, rock crevices) potentially resulting in roost abandonment. Bats may also roost in project infrastructure (e.g., buildings, turbines, road culverts) potentially attracting them to risky locations.	2	2	3	2	2	2	22	-	Low	Minimise disturbance and destruction of farm buildings on site, minimise removal of trees, minimise blasting and removal of rocky habitat on site, and where this is required, these features should be examined for roosting bats. No placement of turbines within no-go areas. Limit potential for bats to roost in project infrastructure (e.g., buildings, turbines, road culverts).	1	1	1	1	1	1	5	-	Low

6.2.2 Operational Phase

Direct impacts to bats during the operational phase are mortality through collisions and/or barotrauma. An Indirect impact is light pollution from artificial lighting associated with project infrastructure, primarily at operation and maintenance buildings, and not turbine aviation lighting. Lighting impacts are included in the operational phase since this is when these issues would occur even though the mitigation of this impact will need to be implemented during the construction phase via the installation of appropriate lighting infrastructure.

ENVIRONMENTAL PARAMETER	ISSUE / IMPACT / ENVIRONMENTAL EFFECT/ NATURE	ENVIRONMENTAL SIGNIFICANCE BEFORE MITIGATION									RECOMMENDED MITIGATION MEASURES	ENVIRONMENTAL SIGNIFICANCE AFTER MITIGATION								
		E	P	R	L	D	I / M	TOTAL	STATUS (+ OR -)	S		E	P	R	L	D	I / M	TOTAL	STATUS (+ OR -)	S
Operational Phase																				
Bat species	Bat mortality (direct impact) through collisions and/or barotrauma with wind turbine blades	2	4	2	3	3	2	28	-	Medium	Implement post-construction fatality monitoring and apply curtailment or deterrents if fatality thresholds are exceeded.	1	3	1	3	3	1	11	-	Low
Bat and insect species	The installation of lighting in the landscape at non-turbine project infrastructure can attract insects and in turn foraging bats, bringing them into the vicinity of wind turbines. Insects can also die at lighting infrastructure, removing bat prey resources.	2	2	2	2	3	2	22	-	Low	Use as little lighting as possible, maximise use of motion-sensor lighting, avoid sky-glow by using hoods, use low pressure sodium and warm white LED lights.	1	1	1	1	3	1	7	-	Low

6.2.3 Decommissioning Phase

Impacts during the decommissioning phase will be indirect and involve disturbance to bats through excessive noise and dust, and damage to vegetation.

ENVIRONMENTAL PARAMETER	ISSUE / IMPACT / ENVIRONMENTAL EFFECT/ NATURE	ENVIRONMENTAL SIGNIFICANCE BEFORE MITIGATION									RECOMMENDED MITIGATION MEASURES	ENVIRONMENTAL SIGNIFICANCE AFTER MITIGATION								
		E	P	R	L	D	I / M	TOTAL	STATUS (+ OR -)	S		E	P	R	L	D	I / M	TOTAL	STATUS (+ OR -)	S
Decommissioning Phase																				
Bat species	Disturbance to bats due to decommissioning activities through noise and dust, and damage to vegetation	2	2	1	2	2	1	9	-	Low	Avoid decommissioning activities at nights, rehabilitate vegetation once project infrastructure removed.	1	1	1	2	1	1	6	-	Low

6.2.4 Cumulative Impacts

Cumulative impacts were assessed by considering impacts from other renewable energy facilities within a 35 km radius from the PAOI. With reference to the Renewable Energy Application database (Q3, 2021), three projects are relevant to this assessment:

1. Proposed 300 MW Paulputs Wind Energy Facility (WEF) and Associated 132 kV Grid Connection, Northern Cape Province (DEA Reference 14/12/16/3/3/2/1120)
2. Proposed wind energy facility and associated infrastructure on Namies wind farm Pty Ltd, near Aggeneys, Northern Cape Province (DEA Reference 14/12/16/3/3/2/550)
3. Proposed 140MW Poortjies Wind energy facility, near Pofadder in the Northern Cape (DEA Reference 14/12/16/3/3/2/681)

In addition, cumulative impacts were also assessed with consideration of the Pofadder WEF 1 and Pofadder WEF 2 projects which will be developed concurrently with Pofadder WEF 3.

ENVIRONMENTAL PARAMETER	ISSUE / IMPACT / ENVIRONMENTAL EFFECT/ NATURE	ENVIRONMENTAL SIGNIFICANCE BEFORE MITIGATION									RECOMMENDED MITIGATION MEASURES	ENVIRONMENTAL SIGNIFICANCE AFTER MITIGATION

6.3 Comparative Assessment of Alternatives

6.3.1 No-Go Alternative

Since the principal risk to bats from wind farms is collision (Arnett and Baerwald 2013), not developing the Pofadder WEF 3 would mean the identified impacts to bats would not occur and the current social-ecological dynamics of the PAOI would be maintained. The same would apply with respect to cumulative impacts to bats of the five WEFs within the cumulative impact region should these not be developed either.

7. MONITORING AND MITIGATION REQUIREMENTS

The following is a summary of the mitigation measure that must be implemented during each phase of the development, and which must be included as conditions in the environmental authorization.

7.1 Construction Phase

- No placement of turbines within no-go areas. WTG63, WTG75, WTG77 and WTG79 must be relocated.
- Minimise clearing of vegetation and removal of trees.
- Rehabilitate all areas disturbed during construction (including aquatic habitat).
- Avoid construction activities at night.
- Minimise disturbance and destruction of farm buildings on site, and where this is required, these features should be examined for roosting bats.
- Minimise blasting and removal of rocky habitat on site, and where this is required, these features should be examined for roosting bats.
- Limit potential for bats to roost in project infrastructure (e.g., buildings, turbines, road culverts) by ensuring these are properly sealed so bats cannot gain access.
- Use as little lighting as possible, maximise use of motion-sensor lighting, avoid sky-glow by using hoods, use low pressure sodium and warm white LED lights.

7.2 Operational Phase

- Implement post-construction fatality monitoring based on best practice standards (Aronson et al. 2020) and apply curtailment or deterrents if fatality thresholds (MacEwan et al. 2018) are exceeded. The implementation of curtailment or deterrents should follow a specifically developed study designed to meet the objectives of lowering bat fatality beyond threshold levels to avoid population level impacts.
- This monitoring requirement and associated mitigation study design (if thresholds are exceeded) must be included in the EMPr. According to the threshold guidance (MacEwan et al. 2018), the bias-adjusted threshold fatality value is 71 individuals per least concern bat species per annum. Should this be exceeded, curtailment and/or acoustic deterrents must be used to reduce fatality levels to below the threshold. One fatality of Angolan Wing-gland Bat (Cistugo seabrae) would trigger the need for mitigation because this species is nationally Near Threatened.

7.3 Decommissioning Phase

- Avoid decommissioning activities at nights.
- Rehabilitate vegetation once project infrastructure removed.

8. CONCLUSION

Based on the pre-construction monitoring data, collision risk to bats is currently predicted to be low up to 50 m and medium at 100 m (Table 3). This reflects the nature of bat activity in the study area which is dominated by high flying bat species, and which were recorded most often at 100 m compared to 10 m and 50 m. Of the range of impacts identified to bats (Table 4), all can be reduced to low with appropriate mitigation measures. This assumes that all mitigation measures are adhered too; specifically:

- ensuring that turbines currently located inside no-go areas are relocated (WTG63, WTG75, WTG77 and WTG79), and that future iterations of the turbine layout ensure the turbine blades of no turbines extend into no-go areas for bats (Figure 6),
- implementing a best-practice fatality monitoring program, and
- using curtailment and/or deterrents if threshold fatality levels are exceeded.

If these are adhered to, the Pofadder WEF 3 can be authorized without unacceptable levels of impacts to bats but pending the outcome of the remainder of the pre-construction bat monitoring. These additional monitoring data will be assessed as part of the final ESIA.

Table 4: Impact Assessment Summary

ENVIRONMENTAL PARAMETER	ISSUE / IMPACT / ENVIRONMENTAL EFFECT/ NATURE	Significance	
		Without Mitigation	With Mitigation
Construction Phase			
Bat habitat features (foraging/commuting habitat)	Vegetation clearing for access roads, turbines and their service areas and other infrastructure, as well as noise and dust generated during the construction phase, will indirectly impact bats by removing habitat used for foraging/commuting and through disturbance.	Low	Low
Bat habitat features (roost habitats)	Construction of WEF infrastructure could result in destruction (direct impact) of bat roosts (trees, rock crevices) and disturbance (indirect impact) of bat roosts (trees, building, rock crevices) potentially resulting in roost abandonment. Bats may also roost in project infrastructure (e.g., buildings, turbines, road culverts) potentially attracting them to risky locations.	Low	Low
Operational Phase			
Bat species	Bat mortality (direct impact) through collisions and/or barotrauma with wind turbine blades.	Medium	Low
Bat and insect species	The installation of lighting in the landscape at project infrastructure can attract insects and in turn foraging bats, bringing them into the vicinity of wind turbines. Insects can also die at lighting infrastructure, removing bat prey resources.	Low	Low
Decommissioning Phase			
Bat species	Disturbance to bats due to decommissioning activities through noise and dust, and damage to vegetation.	Low	Low
Cumulative

8.1 Impact Statement

Based on the impacts assessed, and the implementation of mitigation measures proposed to reduce these impacts, the Pofadder WEF 3 can be authorized without unacceptable impacts to bats pending the outcome of the remainder of the pre-construction bat monitoring.

CURRICULUM VITAE JONATHAN ARONSON

jonathan@camisssaconsulting.com | 062 797 1247 | Amsterdam, Netherlands |www.linkedin.com/in/jbaronson

1 BACKGROUND

Jonathan is a research ecologist with 13 years of experience working on bat and wind energy interactions. He has been at the forefront of bats and wind energy research in South Africa and has worked on more than 100 WEF projects in South Africa, Kenya, Ethiopia, Mozambique, Zambia, Uzbekistan, Azerbaijan, Pakistan, Vietnam, and the UK. He has presented his research at the International Bat Research Conference, the Conference on Wind Energy and Wildlife Impacts, and at numerous local and international bat workshops and symposia.

He is experienced in undertaking pre-construction and operational monitoring projects for bats, impact assessments, mitigation strategy design (including the design of curtailment programs), due diligence exercises, ecological surveys, GIS screening studies and providing strategic advice. He has delivered training to local search teams at operational wind farms in South Africa, Pakistan and Vietnam on bat and bird carcass search methodologies, including providing on-going support and mentoring.

Jonathan has also helped shaped wind-wildlife best practise and policy, co-authoring the Good Practise Guidelines for Surveying Bats at Wind Energy Facilities in South Africa, and developing monitoring guidelines for bat fatality at operational wind power projects. He is a founding member of the South African Bat Assessment Advisory Panel (SABAAP) and a registered as a Professional Natural Scientist (Ecological Science) with SACNASP.

2 PROFESSIONAL HISTORY

Director/Founder, Camissa Sustainability Consulting (2020 - current)
International Finance Corporation (IFC) ESG Sustainability Advice & Solutions Department (2020 - current)
Senior Ecologist, Arcus Consultancy Services South Africa (Pty) Ltd (2019 - 2020)
Ecology Specialist, Arcus Consultancy Services South Africa (Pty) Ltd (2013 - 2019)
Director/Founder, Gaia Environmental Services Pty (Ltd) (2011 - 2013)

3 QUALIFICATIONS

MSc (Environment and Resource Management; Energy and Climate Specialization)
Vrije Universiteit Amsterdam (2020 - 2021)

MSc (Zoology)
University of Cape Town (2009 - 2011)

BSc - Honours (Freshwater Biology)
University of Cape Town (2007)

BSc (Zoology)
University of Cape Town (2003 - 2006)

4 AFFILIATIONS

South African Bat Assessment Advisory Panel (2013 to 2020)
Professional Natural Scientist (Ecological Science) - SACNASP Registration #400238/14

5 PROJECT EXPERIENCE

Research Projects

- Current State of Knowledge of Wind Energy Impacts on Bats in South Africa
- Darling National Demonstration Wind Farm Project. Designed and implemented a research project investigating bat fatality in the Western Cape

jonathan@camisssaconsulting.com | 062 797 1247 | Amsterdam, Netherlands |www.linkedin.com/in/jbaronson

Strategic Advice

- Risk screening for five wind farms in Uzbekistan and Azerbaijan (International Finance Corporation)
- Review of Terms of Reference for Bat Pre-construction Monitoring projects in India (International Finance Corporation)
- Stakeholder Advisory Committee for Good Practices Handbook Post-Construction Monitoring of Bird and Bat Fatalities at Onshore Wind Energy Facilities (International Finance Corporation)
- Review of Bird Fatality data from De Aar 1 and De Aar 2 Wind Farms (Mulilo)
- Management and mitigation recommendations for bats at three proposed wind farms (Rainmaker Energy)
- Peer Review for Three Bat Monitoring Reports for the Bokpoort II Solar Developments (Golder Associates)
- Peer Review of Operational Monitoring at the Jeffreys Bay Wind Farm, including updating the operational mitigation strategy for bats (Globeleq South Africa Management Services)
- Oyster Bay Wind Energy Facility. Reviewing a pre-construction bat monitoring study and providing input into a stand-alone study (RES Southern Africa)
- Review and design mitigation strategies for bats at the Kinangop Wind Park, Kenya (African Infrastructure Investment Managers)

Operational Monitoring Projects for Bats and Birds

- Pakistan Super Six Wind Farms (Consortium of six Companies)
- Loi Hai 2 and Phu Lac 2 Wind Farms (International Finance Corporation)
- Waainek, Chaba and Grassridge Wind Farms (EDF Energy)
- Golden Valley 1 Wind Farm (Biotherm Energy)
- Darling Wind Farm (ENERTRAG)
- Eskom Sere Wind Farm (Endangered Wildlife Trust)
- West Coast One Wind Energy Facility (Aurora Wind Power)
- Fazakerly Waste Water Treatment Works (United Utilities)
- Beck Burn Wind Farm (EDF Energy)
- Gouda Wind Energy Facility (Blue Falcon 140)
- Hopefield Wind Farm (Umoya Energy)

Pre-Construction Monitoring and Environmental Impact Assessments for Bats

Appendix 3: Site Verification Report

SITE SENSITIVITY VERIFICATION (IN TERMS OF PART A OF THE ASSESSMENT PROTOCOLS PUBLISHED IN GN 320 ON 20 MARCH 2020

1 INTRODUCTION

Pofadder Wind Energy Facility 2 (Pty) Ltd is proposing the development of a commercial Wind Energy Facility (WEF) and associated infrastructure, Pofadder WEF 3, on a site located approximately 20 km Southeast of Pofadder within the Kai !Garib Local Municipality and the Z F Mgcawu District Municipality in the Northern Cape Province, South Africa.

In accordance with Regulation 16(1)(b)(v) of the EIA Regulations, a Screening Report is required to accompany any application for Environmental Authorisation. The National Web based Environmental Screening Tool[1] was used to generate this Screening Report for the Pofadder WEF 3. Subsequently, this document presents a site sensitivity verification (SSV) to confirm the current land use and environmental sensitivity of the proposed project area as identified by Screening Tool.

2 SITE SENSITIVITY VERIFICATION

The SSV was undertaken at the desktop level as well as using on-site information collected as part of the 12-month pre-construction bat acoustic monitoring being undertaken for the project in accordance with best practise standards for wind energy projects (MacEwan et al. 2020). The Project Area of Influence (PAOI) was defined as the project boundary plus a 10 km buffer[2] given that bats are volant mammals.

Desktop resources included published scientific articles, texts (Monadjem et al. 2010, Child et al. 2016, Monadjem et al. 2020), and databases (ACR 2020, IUCN 2021) on South African bats. These were used to determine which bat species (i.e., impact receptors) are likely to occur at the project as well as to provide information on their natural history and conservation status.

The acoustic monitoring data were used to confirm species occurrence at the project as well as the magnitude of bat activity. It commenced on 29 June 2021 and bat activity is being sampled at five locations, nightly from sunset to sunrise. Locations were chosen based on a provisional turbine layout to sample bats in areas representative of where turbines might be installed. Two locations are sampling bats at approximately ground level (10 m) while at three locations, sampling is being undertaken simultaneously at 50 m and 100 m. In addition, eight buildings at a farmstead within the project boundary were systematically surveyed on 26 August 2021. The surveys aimed to directly observe roosting bats, locate evidence of roosting bats (e.g., culled insect remains, fur-oil-stained exit and entry points, guano/droppings), and assess the potential for each building to support bats.

As per the Species Environmental Assessment Guideline (SANBI 2020), the best practise bat guidance was used to assign sensitivity to the impact receptors (specifically bat species) in the PAOI. Sensitivity was obtained by calculating the median number of bat passes/hour per night (n = 157 sample nights) pooled across all monitoring locations and bat species but separated by height. These were then compared to the reference values in the bat guidelines to assign a sensitivity rating to the PAOI (Table 1).

Table 1: Height-specific bat activity (passes/hour) and fatality risk for the Nama Karoo Biome

Height Category	Fatality Risk (Sensitivity)		
	Low	Medium	High
Ground level	< 0.18	0.18 – 1.01	> 1.01
Rotor sweep	< 0.03	0.03 – 0.42	> 0.42

[2] In line with guidance for wind farms in the United Kingdom (Scottish Natural Heritage (SNH) 2019)

3 ASSUMPTIONS AND LIMITATIONS

Acoustic monitoring for bats allows for rapid, passive collection of a large volume of bat activity data which can help identify the bat species present within a particular location and their associated relative spatio-temporal activity patterns. In the context of wildlife and wind farm interactions, acoustic monitoring is therefore a useful technique however, there are several constraints (Brigham et al. 2004, Kunz et al. 2007, Adams et al. 2012, Voigt et al. 2021). Acoustic monitoring cannot provide an indication of bat abundance or population size at a site. In addition, population demographics such as age and sex of bats cannot generally be determined from echolocation calls. Species identification is challenging given the variation individual species display in their echolocation call structure and overlap in these structures between species. Echolocation data are thus not as reliable as an identifier of bat species compared to live trapping. To identify species, this study used the Wildlife Acoustics Inc. library “Bats of South Africa Version 5.4.0”, but this excludes reference calls for most South African species thus echolocation recordings were also reviewed manually. Lastly, bat activity is notably variable in response to several factors such as land use change, climactic variability, variations in prey abundance and meteorological conditions which can vary over different time scales. Since this SSV is based on six of months (winter and spring) the bat species inventory of the site may not be complete.

4 OUTCOME OF SITE SENSITIVITY VERIFICATION

The PAOI is situated in the Nama Karoo Biome and the landscape is characterised by open, relatively flat, and sparsely vegetated plains with mountainous terrain in the north and northwest. The vegetation is dominated by Bushmanland Arid comprising low growing shrubs and bunch grasses at low density. Bushmanland Basin Shrubland and Bushmanland Inselberg Shrubland bisects the middle of the PAOI, and Eastern Gariep Rocky Desert vegetation occurs in the north. Sheep farming is the primary land use.

Roost sites in the project are relatively limited and unlikely to support large congregations of bats. The closest known major bat roosts are approximately 120 km northeast of the PAOI. Rocky outcrops are present primarily in the north and northwest and these geological features may provide roosting species for species such as Roberts’s Flat-headed Bat that roost in rocky crevices. Bats are also likely to roost in buildings associated with farmsteads within and bordering the project especially Cape Serotine and Egyptian Free-tailed Bat. Trees growing at these farmsteads, and in limited places elsewhere on site usually at livestock kraals, could also provide roosting spaces for bats although the extent of this is likely limited since these trees are typically not large. The building inspections on site did not reveal any evidence of roosting bats. Sensitive features in the PAOI at which bat activity may be concentrated include farmsteads, farm dams, and the livestock kraals. The presence of water, vegetation and lighting at these features could promote insect activity and hence attract foraging bats. Activity could also be concentrated along the non-perennial Karoep and Soutputs se Laagte rivers which flow through the northeast and south of the project respectively.

Based on current taxonomic information and bat occurrence data, 8 bat species could occur at the project, four of which have been confirmed based on the acoustic data recorded thus far (Table 2). No Threatened species were recorded or expected to occur on site but based on habitat suitability modelling (Monadjem et al. 2010), it is possible that the distribution of the nationally Near Threatened Angolan Wing-gland Bat (*Cistugo seabrae*) may overlap with the project but there is little information on the natural history of this species (Jacobs et al. 2016). It is endemic to the west coast of southern Africa from northern South Africa to southern Angola, and the PAOI is located at the extreme southern edge of its distribution (Figure 1). The closest known localities of this species to the PAOI are between 85 km and 100 km north of the project near the Orange River (ACR 2020). This species is currently considered to be at low risk of wind energy impacts (MacEwan et al. 2020).

The preliminary acoustic monitoring results show that the median number of bat passes/hour per night at height (50 m and 100 m) was 0.1 which would classify the PAOI as medium sensitivity (Table 1). Based on ground level data median pass/hour was 0.0 resulting in low sensitivity. Since the impact (i.e., direct fatality) of the project infrastructure would primarily occur at height, the medium sensitivity rating would be applicable to the PAOI.

Table 2: Bat Species Potentially Occurring at Pofadder 2 WEF

Family	Common Name	*Species Name*	Conservation Status		WEF Risk[δ]	Habitat Requirements*	Prob. of Occurrence	Rationale
			IUCN†	RSA*				
Miniopteridae	Natal Long-fingered Bat	*Miniopterus natalensis*	LC/ Unknown	LC	High	Temperate or subtropical species. Primarily in savannas and grasslands. Roosts in caves, mines, and road culverts. Clutter-edge forager.	Low	Lack of suitable roosts (cave-dependent).
Vespertilionidae	Cape Serotine	*Laephotis capensis*	LC/ Stable	LC	High	Arid semi-desert, montane grassland, forests, savanna and shrubland. Roosts in vegetation and human-made structures. Clutter-edge forager.	**Confirmed**	Echolocation calls recorded.
Molossidae	Egyptian Free-tailed Bat	*Tadarida aegyptiaca*	LC/ Unknown	LC	High	Desert, semi-arid scrub, savanna, grassland, and agricultural land. Roosts in rocky crevices, caves, vegetation, and human-made structures. Open-air forager.	**Confirmed**	Echolocation calls recorded Suitable habitat and roosts.
Molossidae	Roberts's Flat-headed Bat	*Sauromys petrophilus*	LC/ Stable	LC	High	Wet and dry woodlands, shrublands and Acacia-wooded grasslands always in areas with rocky outcrops and hills. Roosts in narrow rock crevices and fissures. Open-air forager.	**Confirmed**	Echolocation calls recorded Suitable habitat.
Vespertilionidae	Long-tailed Serotine	*Eptesicus hottentotus*	LC/ Unknown	LC	Medium	Montane grasslands, marshland and well-wooded riverbanks, mountainous terrain near water. Roosts in caves, mines, and rocky crevices. Clutter-edge forager.	**Confirmed**	Echolocation calls recorded. Suitable roosts.
Cistugidae	Angolan Wing-gland Bat	*Cistugo seabrae*	LC/ Unknown	NT	Low	Limited knowledge of habitat and ecology. All records are in arid areas with mean annual rainfall < 100 mm. Previously captured in riverine vegetation along dry riverbeds and close to open water. Clutter-edge forager.	Low	Edge of range (Figure 1)
Nycteridae	Egyptian Slit-faced Bat	*Nycteris thebaica*	LC/ Unknown	LC	Low	Savannah, desert, arid rocky areas, and riparian strips. Gregarious and roosts in caves but also in mine adits, Aardvark holes, rock crevices, road culverts, roofs, and hollow trees. Clutter forager.	High	Common throughout range. Closest record 38 km north of PAOI (ACR 2020).
Rhinolophidae	Damara Horseshoe Bat	*Rhinolophus damarensis*	LC/ Unknown	LC	Low	Arid savannah and shrubland habitats within the Nama-Karoo Biome. Roosts in caves and mine adits. Clutter forager. Little is known about abundance or population trends of this species.	Medium	Suitable habitat but no suitable roosts. Closest record 64 km west of PAOI (ACR 2020).

LC = Least Concern; NT = Near Threatened
*Based on Child et al. (2016)
†Based on IUCN (2021)
[δ]Based on MacEwan et al. (2020)

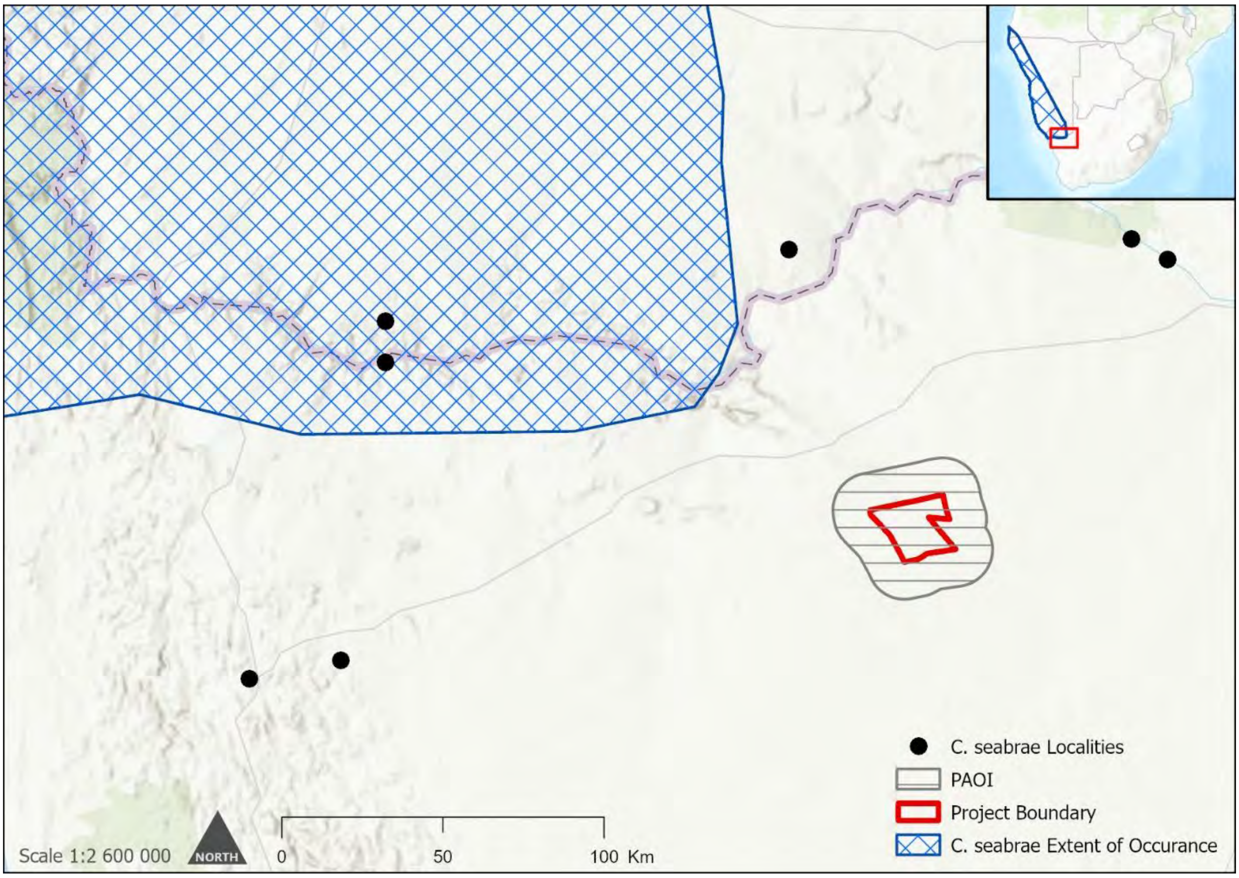

Figure 1: Extent of Occurrence and Locality Records of Angolan Wing-gland bat (*Cistugo seabrae*) relative to the Project Area of Influence (PAOI).

5 NATIONAL ENVIRONMENTAL SCREENING TOOL

The Screening Tool classified areas within the site boundary as medium and high sensitivity according to the Bats theme (Figure 2). High sensitivity features were wetlands and rivers buffered by 500 m, with the remaining areas classified as medium. As a result, the PAOI is classified as high sensitivity overall[3]. The tool did not reveal the presence of any species of conservation concern (SSC).

The outcome of the SSV is that the overall sensitivity of the site is classified as medium, lower than the high sensitivity rating given by the Screening Tool. However, the two sensitivities are based on different data types. The Screening Tool is based on broad scale habitat data whereas the SSV is based on bat collision risk with wind turbines derived from activity data collected within the project boundary and is therefore a better approximation of the project sensitivity because collision is the primary impact. As such the SSV disputes the current environmental sensitivity of the proposed project area, arguing that the sensitivity should be reduced to medium.

[3] In accordance with Government Notice No. 1150 (30 October 2020) Protocol for the Specialist Assessment and Minimum Report Content Requirements for Environmental Impacts on Terrestrial Animal Species (Table 1, 1.6): "If any part of the development falls within an area of confirmed "very high" or "high" sensitivity, the assessment and reporting requirements prescribed for the "very high" or "high" sensitivity, apply to the entire development footprint."

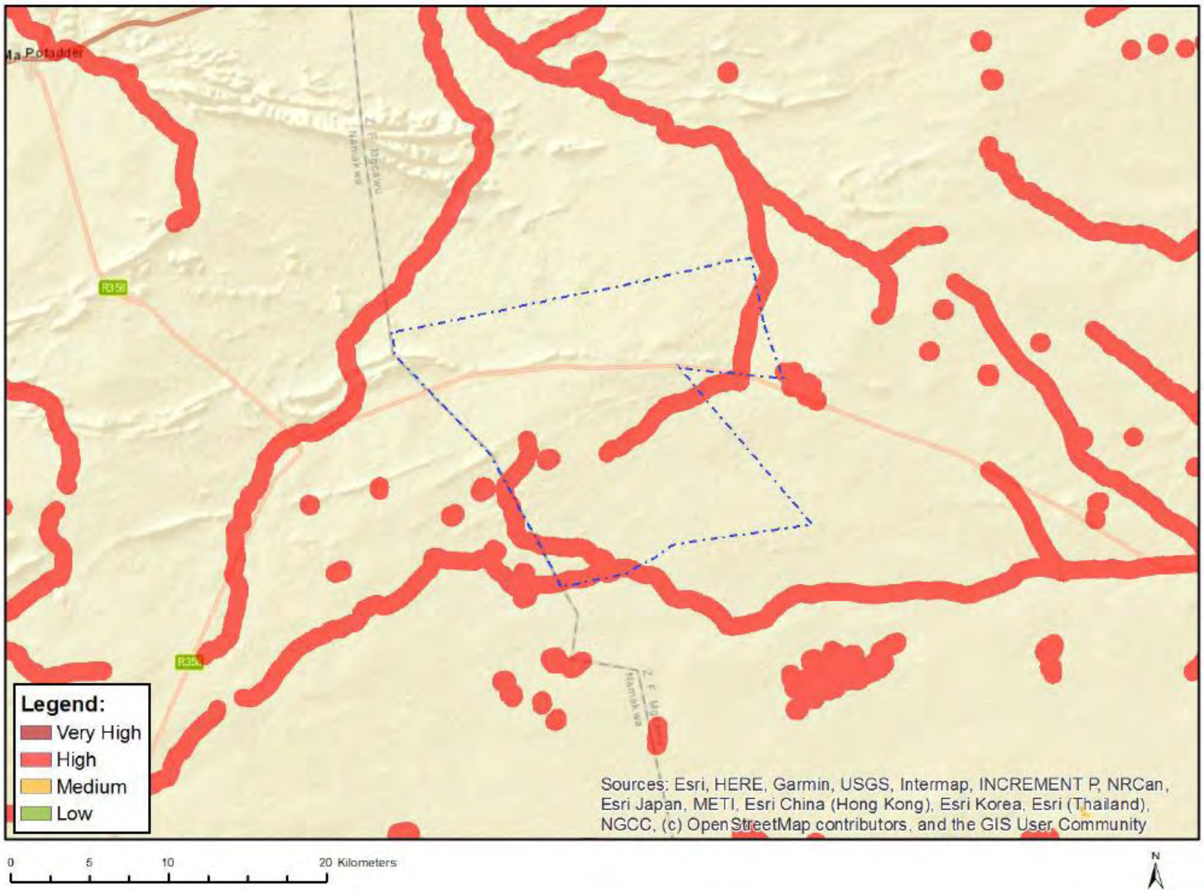

Figure 2: Map of Bats (Wind) Theme Sensitivity

6 CONCLUSION

This document presents a site sensitivity verification (SSV) to confirm the current land use and environmental sensitivity of the proposed Pofadder WEF 3 as identified by National Web based Environmental Screening Tool. Based on the Screening Tool the PAOI is classified as high sensitivity overall. The SSV argued that based on bat collision risk with wind turbines the environmental sensitivity of the PAOI should be classified as medium. As per best practise (MacEwan et al. 2020) a Bat Specialist Assessment is being undertaken for the project.
