5.3 Formation Layerworks Materials
5.4 Foundation Conditions at Structures
4. RECOMMENDATIONS AND CONCLUSIONS
APPENDIX A Schematic Layout and Site Drawing B Detailed Test Pit and Borehole Profiles C DCP Test Results

D Laboratory Test Results

E Photographic Record

# GEOTECHNICAL INVESTIGATION AT LEPHALALE YARD 

## 1. INTRODUCTION AND SCOPE OF WORK

The Waterberg complex is a strategic growth node for various activities within the mining and industrial sectors. Adequate rail infrastructure capacity is deemed critical to unlock the potential of this economic hub. The Waterberg region represents an in-situ coal resource in excess of 76 billion tons, and is expected to experience significant growth in coal and mineral production over the next 20 years. The purpose of rail expansion from Waterberg is to provide infrastructure along the coal railway line to increase the coal hauling capacity. In recent years there have been numerous requests from industry for an assessment and subsequent supply of long term rail network capacity from the Waterberg area to Richards Bay and Maputo, for export, and to various inland destinations, for the domestic market.

The Waterberg rail infrastructure upgrade is to meet the increased coal tonnage demand. The work to achieve this objective is planned to be carried out in stages over a number of years. Transnet Group Capital (TGC), is providing professional engineering services for the doubling of the existing Transnet Freight Rail's railway line with the Geotechnical Office of TGC executing the geotechnical investigation.

Transnet Group Capital (TGC), PD\&E (Geotechnical) was approached by TGC Project Management in Johannesburg to conduct a geotechnical investigation for additional tracks at various distances from the existing track between kilometres 96.00 and 101.00 as well as for various facilities. The scope for this geotechnical work required for the FEL3 study, can be described as follows:

- Determine the nature, distribution and relevant applicable engineering properties of the near surface soil strata along the proposed new alignment of the loop
- Evaluate the near surface soil conditions in order to be able to classify the soils and provide recommendations for the railway formation layerworks. The formation layerworks are to meet the requirements of the Specification for Railway

Earthworks S410, (Grabe and Maree, March 2006) for a 20 t axle loading line in a moderate climate

- Evaluate the near surface soil conditions in order to provide recommendations for founding of various culverts
- Submit a geotechnical interpretative report containing all the relevant information.

Layout and long section drawings no. 3424302-4-1A6-N-LA-0002, sheets 01 to 10 , rev 1 by DJ prepared and issued by TGC Perway Office has subsequently been used during the fieldwork phase and to present the geotechnical information completed. The site drawing is included in Appendix A of this report.

This report covers the nature and findings of the geotechnical investigation that was carried out and presents the results and findings of the fieldwork and laboratory testing, the evaluation of the results and recommendations for railway formation layerworks, maintenance roads and structures.

## 2. SITE LOCATION, DESCRPITION AND PROPOSED DEVELOPMENT

The site is located approximately 30 km west of the town of Lephalale (Ellisras) at starting point $\left(23^{\circ} 46^{\prime} 51.35^{\prime \prime} \mathrm{S}, 27^{\circ} 25^{\prime} 52.19^{\prime \prime} \mathrm{E}\right)$ and end point $\left(23^{\circ} 44^{\prime} 53.14 " \mathrm{~S}\right.$, $27^{\circ} 28^{\prime} 24.859 " E$ ) on the single railway line between Thabazimbi to Lephalale.

In general, topographically the Lephalale site is generally flat and slightly undulating with the highest points on the eastern and western perimeters, sloping gently towards the center in the direction of a major culvert at chainage $\mathrm{Km} \mathrm{99+200}$. The existing formation level along the existing railway line's alignment over this new length is located on fills (embankments of up to approximately $\pm 4.0 \mathrm{~m}$ in height) with sections at grade and cuts (maximum depth in the order of $\pm 10.0 \mathrm{~m}$ ).

Game farms border the site on either side while the typical vegetation consists mostly of sparse grasses, shrubs and typical bushveld trees. Hard rock sandstone boulders outcrop at surface and in existing cuttings along the railway line, while no bedrock was observed.

Existing services encountered on site include the non-electrified railway line, along with a gravel service road located on the southern side and level crossings (at chainage Km $100+560)$ and several culverts.

The development of the site will comprise of a yard with several railway lines proposed and entail the following:

Southern section consisting of:

- A bypass line
- Decanting arrival/departure lines (2 No.)
- Departure line.

Northern section consisting of:

- An arrival line (denoted arrival line 1)
- Run around line
- $\quad$ Spare lines (3 No.).

The abovementioned sections are referenced to the existing main line or referenced as Arrival line 2 on the layout drawings.

In addition to the yard, several facilities are also proposed and comprise of single storey buildings, a rail over road bridge and fuel storage tanks.

The structures will be at the following chainages:

- Provisioning facility on main line between Km 97+800 and Km 97+900
- Provisioning facility on main line between Km 99+120 and Km 99+220
- Admin/Operations building and staff amenities adjacent to main line between chainages $\mathrm{Km} \mathrm{99+240}$ and $\mathrm{Km} \mathrm{99+340}$
- Infra office and amenities adjacent to the bypass line at chainages Km 3+140 and Km 3+180
- Rail over road bridge on bypass line at chainage $\mathrm{Km} \mathrm{3} 3+480$
- Fuel Storage tanks between bypass line and main line at chainage Km 98+500.

At the time of the geotechnical investigation, no evidence of water ponding or seepage was observed during the investigation along the railway line.

A schematic layout of the proposed developments is given in Appendix A and photographs of the site at the time of the fieldwork are presented in Appendix E.

## 3. NATURE OF THE INVESTIGATION

The geotechnical investigation made use of both field and laboratory testing methods in order to determine the nature and distribution of the soil/rock strata underlying the site. The investigation was a phased approach comprising of Phase 1 (or Southern section), Phase 2 (or Northern section) and Phase 3 for the proposed structures.

### 3.1 Fieldwork

The fieldwork was carried out during June to August 2017 and several test pits ( $\pm 93$ No.) were set out, as per the layout/section drawings provided TGC Perway Office, along the various alignment routes of the proposed railway lines and proposed structure locations. Almost all the test pits were excavated by means of a tractor-mounted loader backhoe (TLB) model CAT 428E, with the exception of in isolated sections were hand excavated pits were required due to restricted access of the TLB machine. All test pits were profiled in-situ immediately after excavation and the soil profiles were recorded in detail using the recognised standard method for soil profiling given in the Revised Guide to Soil Profiling for Civil Engineering Purposes in Southern Africa. The parameters that were recorded are moisture content, colour, consistency, soil structure, soil type and origin. Representative disturbed samples were also recovered for laboratory testing purposes during this test pitting phase.

One metre long hand-held Dynamic Cone Penetrometer (DCP) tests were done next to each test pit from the existing ground surface level. The tests were performed to determine the in-situ strength of the near surface soils and were done to either refusal or a maximum depth of 1.0 m . The advance of the cone for every 5 blows of the falling weight was recorded.

Thirty two ( 32 No.) rotary cored boreholes were formed at proposed cutting sections to be widened and major structures in order to determine the nature and relevant engineering properties of the soil/rock strata below the depth limit of the test pits.

Eighteen (18 No.) boreholes were drilled vertically while the remaining fourteen (14 No.) were drilled at an inclination of $60^{\circ}$. The holes were advanced using standard wash boring techniques with standard penetration tests (SPT's) at 1.5 m intervals in the vertical boreholes up to where refusal occurred in the Residual Sandstone and/or Sandstone boulders/bedrock. Core samples from the underlying Sandstone bedrock were recovered using rotary core drilling.

Standard Penetration Tests (SPT samples) and core extracted from the rotary core drilling were profiled/logged in accordance with standard method of soil profiling and core logging procedures used for civil engineering purposes in South Africa.

The detailed test pits and borehole drilling logs with attributes, levels, reduced levels and co-ordinates as well as the DCP test results and graphs are presented in Appendix B and C respectively.

## Laboratory Testing

Selected soil samples from the test pits were submitted for laboratory testing purposes. The following engineering tests were carried out:

Particle size grading analysis, including hydrometer analysis

- Atterberg Limits
- Moisture content and density (Modified AASHTO effort) relationship
- California Bearing Ratio (CBR)
- Natural moisture content
- Unconfined Compressive Tests (UCS) on rock samples.

Copies of the laboratory test results are presented in Appendix D. Where applicable, the laboratory test results are summarized in tables and included in the relevant sections of the report.

## 4. SITE GEOLOGY

### 4.1 Regional Geology

The general area is underlain by sedimentary rocks of the Waterberg Group comprising of sandstone and conglomerates. The various rock types are generally covered by a wide range of materials such as residual soils, and/or pedogenic soils overlain by transported soils and occasional fill. The layer thicknesses are highly variable.

### 4.2 Subsoil/rock Conditions

For ease of reference, the general occurrences of the various soil/rock horisons encountered on site have been summarised in the tables below. Depths are measured from existing ground level at the time of the fieldwork.

The remarks column provides a description of the existing earthworks and/or structures relative to natural ground level. (Information relevant to the bypass line is given in Italics).

Table 4.2.1: Summary of shallow subsoil/rock conditions encountered during test pitting phase - Phase 1

| Test Pit No. | Position <br> (chainage) | Topsoil/ <br> Fill | Transported <br> (Alluvium) | Reworked/ <br> Residual <br> Sandstone | Remarks |

### 4.3 Ground and Surface Water Conditions

No groundwater seepage or surface water was encountered at the time of the investigation but it should be noted that the investigation was done during the dry season. In addition, the soil profile in some test pits contains pedogenic material (ferruginised nodules) which generally develops when a fluctuating shallow perched water table is present. The occurrence of a shallow perched water table can be expected especially during and/or after periods of heavy and/or continuous rainfall.

## 5. GEOTECHNICAL EVALUATION

### 5.1 Excavation Classification

Excavation procedures likely to be encountered on the site have been evaluated in terms of the SANS 1200D - Earthworks classification system. In terms of this classification system, soft excavation conditions are expected in the Topsoil/Fill/Transported and Reworked/Residual Sandstone within a variable depth range of 0.50 m and beyond 3.20 m below NGL. Below these depths, intermediate and/or hard (sporadically boulder) rock excavation in terms of the abovementioned standard occurs on the Sandstone boulders and/or bedrock with typical Unconfined Compressive Strength (UCS) values in the range of 32 MPa to 127 MPa .

Excavation on site could be hampered by the presence of shallow/standing water particularly at culverts and should be taken into account, while overbreak of excavation sides may occur (due to the loose consistency of some soils). In addition, care must be taken so that the integrity of the adjacent railway line is not compromised at any stage during the excavation and construction in close proximity. Safe passage of trains should be guaranteed at all times during the construction period.

### 5.2. In situ Strength of Subsoils

The results of the DCP field tests have been used to evaluate the in-situ strength or CBR values of the near surface subsoils for Phase 1 and 2. Cognisance of the moisture content and potentially gravelly nature of the subsoils in the soil profile should be taken into account when using these DCP -derived CBR values. The results of the DCP tests are given in Appendix C and should be referred to for specific details.

The tables below summarise all the DCP test results in terms of the average in-situ CBR values with depth for tests conducted from surface. The tables present the average CBR obtained from the in-situ DCP test values at specific depth intervals with different colours denoting the different layers as specified in the Railway Specifications for Earthworks S410. The summarised tables do not include the laboratory results, which mean it does not take certain parameters such as the plasticity index into account. Below the tables, a legend specifying the various colours according to the obtained CBR values is presented.

Table 5.2.1: Summary of average in-situ CBR Value (\%) from surface - Phase 1

### 5.3 Formation Layerworks Materials

The laboratory tests results have been used to evaluate and classify the near surface in-situ soils for their suitability for re-use in the formation layerworks and should be referred to for specific details, as contained in Appendix D. A summary of the classification of the soils encountered at each test pit for possible re-use in the construction of the formation layers and optimum/natural moisture content is given below.

The main criteria for the classification were based on the CBR compacted strength of the various soil horisons. In general, certain materials do not fully meet the specifications with respect of its grading modulus and grading envelopes and plasticity index (PI)>

Table 5.3: Summary of Results of Particle Size Distribution Analysis and Atterberg Limit Determinations, Compaction, CBR

### 5.4 Foundation Conditions at Structures

The alignment for this proposed new loop is such that several pipe/box culverts exist along the proposed development. Based on the results of the fieldwork, it is apparent that all the subsoils encountered at these locations influence the founding conditions. The test pits dug at these culverts reveal variable and generally loose to medium dense Topsoil, Fill and Transported horisons and are considered unsuitable founding horisons. Ideally foundations should be placed at an average depth of 0.85 m on more competent subsoil horisons of dense to very dense Residual Sandstone.

It is generally understood that in general cut to fill and/or fill procedures will be carried out for the founding of the proposed structures and these are likely to impact on the anticipated founding depths. Actual founding depths will depend on the final cut and/or embankment levels. Using the information summarised in table 4.2.6, the proposed structures to be founded in Cut should be placed on the competent dense to very dense Residual Sandstone. For the proposed structures to be placed on Embankment materials due diligence will need to be given, specifically to the design of embankments in order to avoid excessive founding depths and potential settlements.

The exact loads for the proposed structures were unknown at the time of writing this report. The above should only be used for conceptual design and must be revised when the actual foundation configuration and loads are known. As part of the design of the foundations, calculations for bearing capacity failure must also be conducted.

The settlement of a foundation is almost always the governing criteria and it is therefore proposed that the bearing capacity evaluation be conducted for the actual foundation configurations loads.

## 5. RECOMMENDATIONS AND CONCLUSIONS

The proposed development of Lephalale Yard and the recommendations given below need to be implemented in terms of the S410 Specification for Railway Earthworks. The specified layerworks for unstabilised layers for 20 ton axle loading conditions will apply:

In accordance with the abovementioned criteria, the following general earthworks considerations are recommended for the proposed yard:

- Embankment sections (up to $\pm 4.0 \mathrm{~m}$ high) the following are recommended:
- Remove (to stockpile for re-use) any topsoil/fill with grass and roots
- Compact in-situ soil to achieve a minimum CBR of $5 \%$
- Import and construct appropriate layerworks including Bulk Earthworks B, A and SB (sub-ballast) formation layers according to the Specification for Railway Earthworks S410 (Grabe \& Maree, 2006). For example, in application this will require the imported SB (sub-ballast) material to have a PI of between 3 and 10, a minimum grading modulus of 1,8 and a CBR of not less than $45 \%$, compacted to a minimum of $95 \%$ Mod AASHTO density.

## $>$ Cutting sections of up to $10 . \mathrm{m}$ deep:

- Remove (to stockpile for re-use) any topsoil with grass and roots
- Excavate (for a 4 m wide strip at 2.6 m from the centerline of the existing track) to a level equivalent to 0.9 m below final formation level. When encountered, large sandstone boulders and/or bedrock to be excavated to the required depth. Blasting may be required. If due to blasting the cutting is over excavated, the A layer must be provided and placed before construction of the SB layer commence. The depth of the cut will vary along the doubling according to the variation in ground level relative to the top of rail level
- Where possible (based on the geotechnical investigation this in-situ material is expected to comprise of dense to very dense silty sand/sand (occasionally gravels) and/or soft to hard rock sandstone boulders/rock), compact in-situ material to a minimum $90 \%$ Mod AASHTO density, if complying to the requirements for Bulk Earthworks layer
- Import and construct appropriate including $\mathrm{B}, \mathrm{A}$ and SB (sub-ballast) formation layer according to the S410 Specification for Railway Earthworks (March 2006). The imported SB (sub-ballast) material shall have a PI of between 3 and 10, a minimum grading modulus of 1,8 and a CBR of not less than $45 \%$, compacted to a minimum of $95 \%$ Mod AASHTO density.

## $>$ Level/Cut sections $(<1.0 \mathrm{~m}$ deep $)$

- Remove (to stockpile for re-use) any topsoil with grass and roots.
- Excavate to a level equivalent to $0,90 \mathrm{~m}$ below final formation level and stockpile material for re-use in isolated sections where needed. The depth will be different depending on the ground level and the required height of the rail.
- Compact in-situ material to a minimum of $90 \%$ Mod AASHTO to achieve a minimum strength CBR of $5 \%$, if complying with the requirements for Bulk Earthworks layer.
- Import and construct appropriate layerworks including B, A and SB (sub-ballast) formation layers according to the S410 Specification for Railway Earthworks (Grabe \& Maree, 2006).

In general permanent cut and fill slopes are not to be steeper than $1: 2$ and are to include benching where appropriate.

The service road is to be constructed in accordance with the specifications given in the S410 specification. The minimum layers required are the 300 mm thick B-Layer (compacted to a minimum of $93 \%$ Mod AASHTO density) and the 150 mm thick wearing course (compacted to a minimum of $95 \%$ Mod AASHTO density) in accordance with the S410 material specification. The full thickness of the wearing course is to extend above the existing ground level. The foundation beneath the B-layer is to be a 150 mm deep in-situ rip (only in non-cohesive soils) and re-compacted to a minimum of $90 \%$ Mod AASHTO density.

The results of this investigation of the in-situ geotechnical conditions along the alignment for the proposed loop are presented and evaluated in this report. While particular sections are faced with geotechnical conditions that are not conducive to the specific application in the natural condition, these problem areas can be overcome with the use of good engineering design principles and construction methods. These have been presented and discussed in the report and include removal of substandard material and/or thick cohesive horisons (if encountered) in isolated sections and replacement with appropriate quality soil (formation layerworks), provision of water control measures, safe slope angles for excavated cutting slopes and newly constructed embankment slopes, in-situ preparation methods for general earthworks and foundation types for structures.

It should be noted that the information presented in this report and summarised in the tables has been taken from the geotechnical fieldwork and results of the laboratory tests. A certain amount of interpretation was necessary in the generalisation of the results during the evaluation. During construction, site conditions should be constantly monitored to ensure that the actual conditions are not at variance with the generalisations made in this report. Should variations be found, these areas would be treated on an ad hoc basis at the time. The contents of this report are an interpretation of the findings and are therefore not a design report. Consequently, design of the various components of the project such as railway line formation (preparation and layerworks), embankments, cuttings, foundations, 20 ton axle load sections, new turnouts and crossovers should still be carried out.
