EXECUTIVE SUMMARY

DNV GL has conducted a preliminary geotechnical investigation for the proposed Choje Wind Farm. This report follows from the Choje Wind Farm Desktop Report, which provides the background geological information and site description for the project. The preliminary geotechnical investigation (first phase) consisted of nine rotary core boreholes, drilled from surface to a depth of 30m. Boreholes were supplemented by additional trial pit excavation at borehole positions, as well as at the proposed Eastern Block substation and Western Block 400MTS. Trial pits and boreholes were sampled where appropriate and samples submitted for a suite of laboratory-based geotechnical testing. All logs and test results are contained within this report. The study was conducted as an initial early-stage investigation into the variability of sub-surface conditions that may be expected to be encountered across the site. It is intended to be followed by further Preliminary Geotechnical Investigations, as well as then the detailed geotechnical investigation prior to final foundation design.

The results of the preliminary geotechnical investigation indicate that generally hard rock conditions prevail close to surface across the majority (approximately 70%) of the site. The underlying strata consists of sandstone, siltstone, mudstone and tillite. Excavation for founding will necessitate the use of localized blasting or hard excavation to reach anticipated founding depth. In the remaining 30% of ground conditions, very soft rock, deep sands and weathered pedogenic calcrete were encountered. These would require soil improvement methods through an adapted foundation design, the potential shifting of turbine locations to areas of better founding, or the cancellation of turbines located at complex founding sites.

DNV GL has provided recommendations for further geotechnical testing and investigations required at the Choje Windfarm site during supplementary phases of ground investigation.

1 INTRODUCTION

DNV GL South Africa was appointed to conduct early-stage geotechnical investigations at a site in the Eastern Cape, South Africa, in support of the proposed Choje Wind farm development. The project proceeded with a site visit undertaken by DNV GL and Wind Relic (the "Customer"), culminating in the production of PP225941-ZACT-R-01-A Choje Wind Farm Desktop Geotechnical Report in February 2019. The Choje Wind Farm Desktop Geotechnical Report should be read in conjunction with this report for the project background and supporting geological information.

The Choje Wind Farm project will consist of an estimated 3000MW of onshore wind turbines, divided into an Eastern and Western block, located between Grahamstown and Somerset East, Eastern Cape, South Africa. The project is intended to be developed in multiple phases, with initially approximately 550MW in the Eastern Block, and 1250MW in the West. These may be divided into 6 sub-windfarms, of approximately 200-250MW size. Current layout iterations are being conducted by DNV GL, modeled on a series of differing turbine sizes in the 4 – 6MW range. Provisional layouts have been utilised in selecting the drilling and testing positions for this preliminary geotechnical survey. It is conceivable that the positions may shift with further refinement, however this is not a significant concern as the preliminary geotechnical study is not intended to supply point-specific geotechnical data, but rather an initial insight into potential geologies that may be encountered on the site.

The study involved the drilling of 9 HQ-sized rotary core boreholes at proposed turbine positions, 26 trial pits and 26 in-situ Dynamic Cone Penetrator (DCP) tests at turbine locations, crane platforms and substation positions. Selected disturbed samples were retrieved from testing positions for laboratory analysis.

The ground conditions described in this report refer specifically to those encountered in the excavated trial pits and drilled boreholes. It is therefore quite possible that differing conditions may be encountered elsewhere on the sites during construction. There is no warranty that the information is totally representative of the whole investigation area.

1.1 Terms of Reference

DNV GL has been appointed by Wind Relic (the "Customer") to conduct a number of development-phase activities in support of the establishment of the proposed Choje Wind Farm. This includes the preliminary geotechnical investigation report, conducted by DNV GL South Africa in terms of accepted proposal and signed SFA #L2C177021_SA_P_01-A_V1. Subcontractors utilised in support of the production of this report include *Outeniqua Geotechnical Laboratories* of George (geotechnical testing and field support), *ControLab Materials Testing Laboratory* of East London (rock sample testing) and *JG Afrika Engineers* of Durban (geohydrology).

1.2 Technical Investigation Standards

- The geotechnical investigation was performed according to best practice as directed by the following Standards:
- SANRAL, (2010). Standard Specification for Subsurface Investigation;

- Committee of State Road Authorities, (1993). Standard Specification for Subsurface Investigations;
- SABS 1200D (1988). Standardized Specification for Civil Engineering Construction;
- Jennings, J.E., Brink, A.B.A. and Williams, A.A.B. (1973). *Revised Guide to Soil Profiling for Civil Engineering Purposes in Southern Africa*. Transactions of the South African Institution of Civil Engineers, Vol. 15;
- Proceedings of the Symposium on Exploration for Rock Engineering (1976). *A Guide to Core Logging for Rock Engineering*. Core Logging Committee of the South Africa Section of The Association of Engineering Geologists.

2 LOCAL AND REGIONAL GEOLOGY, SEISMICITY AND TOPOGRAPHY

Readers are referred to the previous issued DNV GL report for this project, PP225941-ZACT-R-01-A *Choje Wind Farm Desktop Geotechnical Report* dated 21 February 2019, for comment on previous geotechnical work in the area, local and regional geological environment, seismicity, a description of the topographical conditions, comment on construction materials, and Geotechnical Founding Classes of the Choje Windfarm site.

3 INVESTIGATION METHODOLOGY

The field investigation entailed:

(i) The drilling of nine (9) HQ3-sized boreholes at predetermined WTG foundation positions utilising rotary core drilling methods. Boreholes were drilled vertically, to depths of 30m each;

(ii) The machine excavation of trial pits at predetermined positions at each of the 9 selected turbine positions. One trial pit was excavated within the foundation footprint, and a second trial pit excavated approximately 50 – 70m away at the potential crane platform position;

(iii) The retrieval of selected disturbed subsoil samples and groundwater samples for laboratory analyses;

(iv) The establishment of *in situ* density conditions, where possible, adjacent to excavated trial pits through Dynamic Cone Penetrometer (DCP) testing.

(v) Disturbed samples were retrieved from boreholes and trial pits and submitted to a South African SANAS-Accredited Civil Engineering laboratory (*Outeniqua Geotechnical Laboratories*) in accordance with South African National Standards (SANS) test methods (TMH1 and SANS3001), British Standards (BS) or the American Society for Testing and Materials (ASTM) standards as applicable.

Figure 1 overleaf provides illustrates the positions of all borehole and trial pit investigation points on the site.

3.1 Boreholes

Nine (9) boreholes were drilled at predetermined WTG positions utilising rotary core drilling methods, on a HQ3 drill-string size by the drilling Contractor *EarthTech Geotechnical Services*. Sampling during the exploration was performed using Standard Penetration Test (SPT) where possible, although SPTs widely refused across the site owing to dense residual soils and weathered rock. Split spoon tube sampling was also attempted, however geological conditions did not cater for any successfully being retrieved. The positions of all WTG boreholes are illustrated in Figure 1. The soil conditions and rock strata described using standard methods and terminology outlined by *Jennings et al.* (1973) and the *Core Logging Committee of South Africa* (1976). Borehole logs and photographic plates are included in Annexure B.

Representative soil samples were subjected to laboratory testing, including Particle Size, Atterberg Limits, hydrometer, Moisture Content, whereas representative rock core samples were subjected to Point Load Strength Index and Unconfined Compressive Strength (UCS) tests. Fifty-millimeter standpipes were installed in all boreholes after completion of the drilling and core extraction. Boreholes were flushed after a minimum of three-day period (in order for the drilling fluid *Easimix* to degrade) and then sampled on the recharged groundwater. Groundwater samples were collected from several boreholes for pH and electrical conductivity

(EC) tests to determine the corrosivity (acidity and salinity) of groundwater against buried structures and services.

Plate 1: Rotary core drilling at borehole position E64

3.2 Trial Pits

Twenty-six (26) trial pits were machine excavated at predetermined positions by means of a Tractor-Loader-Backhoe (TLB). The co-ordinate positions of all trial pits are illustrated in the logs attached in Annexure C.

One (1) trial pit, at each of the WTG founding positions was excavated to a depth of 3.00m or refusal, whichever came first. In addition, one (1) trial pit, was excavated approximately 50-70m away at each of the potential crane platform positions. Four (4) trial pits were also excavated as the proposed Eastern Block substation position, to a depth of 3.00m each or refusal, whichever came first. Another four (4) trial pits were additionally excavated at the proposed 400 MTS position on the Western Block.

All trial pits were profiled by and the soil conditions described using standard methods and terminology outlined by Jennings et al. (1973) Representative soil samples retrieved from trial pits were subjected to Modified AASHTO moisture/density, California Bearing Ratio (CBR), Foundation Indicator, Moisture Content, Relative Density and Thermal Resistivity. Representative samples of various soil types were collected for pH and electrical conductivity (EC) to determine the potential aggressiveness (corrosivity) of the soil towards buried structures and underground electrical services.

Plate 2: Trial pit excavation at W417 position *(photo credit: Outeniqua Geotechnical Laboratory)*

3.3 Dynamic Cone Penetrometer (DCP) Tests

DCP tests were conducted adjacent to trial pit at the turbine locations and substation positions. Tests were conducted from the current surface level to depths of 2m or refusal, which ever come first.

An aspect of DCP testing that must always be noted is the climatic condition on the day the tests are undertaken, as precipitation events may adjust the shaft frictional indices and affect results. DCP testing was conducted under *dry conditions* during the Choje Preliminary Study, with no recent rainfall having been recorded in the area. Soil moisture content values were therefore low.

The results of DCP tests are provided in accompaniment to the trial pit logs in Appendix C of this report.

4 TESTING POSITIONS AND ROUTE EXCAVATABILITY

Figure 2 below provides an indication of the borehole and trial pit orientation relationship at WTG E100 position. The remaining 8 borehole/trial pit orientation plots (**Figures 3-10**) are presented in Appendix A.

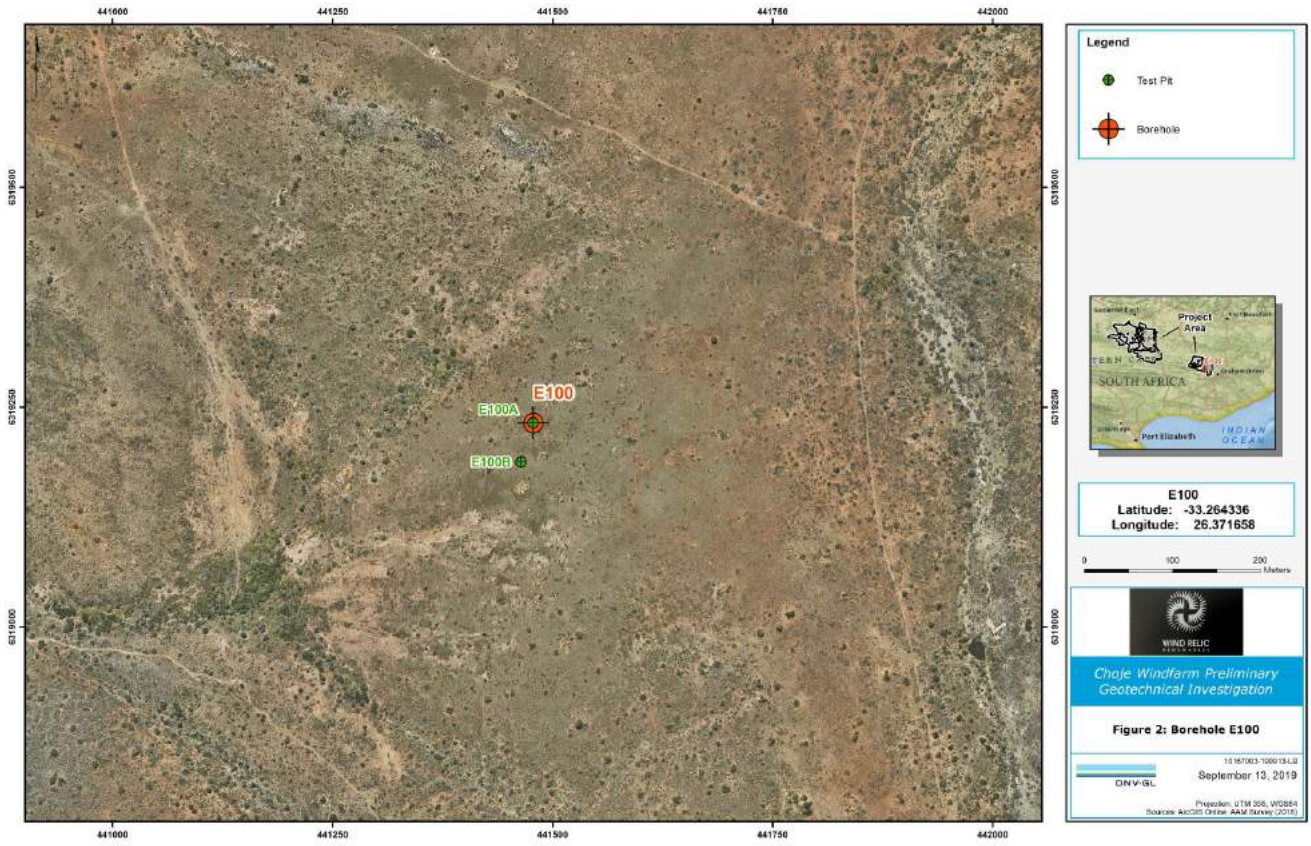

Figure 2: Borehole E100 position plan

Excavatability considerations for the turbine positions and access road routes are described in terms of SABS 1200 D (1988). Excavatability indicates the ease at which *in-situ* material is removed and what excavation methods should be utilised. Excavation classes are provided based upon the ease at which material can be removed by mechanised plant of varying power classes.

4.1 Soft excavation

Soft excavation, other than in restricted excavation, shall be excavation in material that can be efficiently removed or loaded, without prior ripping, by any of the following plant:

i) a bulldozer of mass (including mass of ripper if fitter) approximately 22t and flywheel power approximately 145 kW, or

ii) a tractor-scraper unit of total mass approximately 28t and flywheel power approximately 245 kW, pushed during loading by a bulldozer equivalent to that specified in (b) (1) below, or

iii) (iii) a track type front-end loader of mass approximately 22t and flywheel power approximately 145 kW

In the case of restricted excavation, soft excavation shall be excavation in material that can be efficiently removed by a back-acting excavator of flywheel power approximately 0.1- kW per millimeter of tined-bucket width, without the use of pneumatic tools such as paving breakers.

4.2 Intermediate excavation

Intermediate excavation, other than in restricted excavation, shall be excavation (excluding soft excavation) in material that can be efficiently ripped by a bulldozer of mass approximately 35t, fitted with a single-tine ripper suitable for heavy ripping, and of flywheel power approximately 220 kW.

In the case of restricted excavation, intermediate excavation shall be excavation (excluding soft excavation) in material that requires a back-acting excavator of flywheel power exceeding 0,10 kW per millimeter of tined-bucket width or the use of pneumatic tools before removal by equipment equivalent to that specified in above.

4.3 Hard rock excavation

Hard rock excavation, other than in restricted excavation, shall be excavation (excluding boulder excavation) in material that cannot, before removal, be efficiently ripped by a bulldozer equivalent to that specified in above. It must be noted that such excavation generally includes material such as formations of unweathered rock that can be removed only after blasting.

In the case of restricted excavation, hard rock excavation shall be excavation in material (excluding boulder excavation) that cannot be efficiently removed without blasting or without wedging and splitting.

For the purposes of isolated hard rock excavation, this may also include the use of an excavator-mounted rock hammer (rock pecker).

4.4 Boulder excavation Class A.

Boulder excavation Class A shall be excavation in material containing more than 40% by volume of boulders of size in the range 0,03-20 m^3, in a matrix of soft material or smaller boulders. Excavation of solid boulders or lumps of size exceeding 20 m^3 will be classed as hard rock excavation.

Excavation of fissured or fractured rock will not be classed as boulder excavation but as hard rock or intermediate excavation, according to the nature of the material.

4.5 Boulder excavation Class B.

Boulder excavation Class B shall be excavation of boulders only, which are in a material containing 40% or less by volume of boulders of size in the range of 0,03-20 m^3, in a matrix of soft material or smaller boulders, and which require individual drilling and blasting in order to be loaded by a track type front-end loader or back-acting excavator, as the case may be, as specified in (a) above. The excavation of the rest of the material will be classed as soft or intermediate excavation, according to the nature of the material.
Estimation percentages of excavation classes for the existing access roads on the site are based upon a 1.0m deep roadbed excavation, and reflected below:

	Excavation Class (SABS 1200D)	**Estimated Percentage (%)**
a	Soft excavation	65
b	Intermediate excavation	15
c	Hard excavation	10
d	Boulder excavation Class A	5
e	Boulder excavation Class B	5

It must be noted that the excavation percentages stated above are estimates generated from point-source information in the form of trial pits placed at potential turbine positions and sub-station sites. No guarantee can be provided for variations in excavatability conditions in between trial pit locations.

5 GEOTECHNICAL RESULTS

5.1 Ground Profile

The results of the field studies at the Choje windfarm site allow a general picture of the regional soil and rock conditions to be compiled. The significant size of the project means that the geological terrain varies markedly across the site area, with individual turbine positions sited in deep soils and hard rock alike. General themes for the broad area, however, are consistent and may be informed upon to guide the initial preliminary design of WTG foundations, access roads and structures. Table 5.1 provides a summary of the most significant information gathered from the nine boreholes drilled on the Eastern and Western Blocks.

The local rock types observed in the boreholes consisted of sedimentary rock types sandstone, siltstone, mudstone and shale, as well as a large amount of glacial tillite. The near-surface part of the rock profile demonstrated high to moderate weathering and a tendency for high to moderate fracturing. Rock hardness varies according to rock type, with sandstone and tillite typically being medium to very hard and the argillaceous rocks being very soft to medium hard.

Significant variation in the hardness of the tillite was observed between boreholes (compare logs from E7 and E64), associated with the degree of weathering the tillite has been subjected to under the influence of groundwater. Significant core loss was recorded in a number of the boreholes at shallow founding depth of

2-4m (e.g. E6, W411, W417 – See Appendix B). Core loss in calcareous soils is unsurprising (W417), as fines wash out during the drilling process, however core loss in rock is largely due to the highly fractured, highly weathered and soft nature of shallow rock at these positions.

Table 5-1: Borehole Simplified Results

Borehole No.	***Description***	***Soil Cover Depth***	***SPTs***	***Rock Condition***	***Medium Hard Rock Depth***	***Groundwater Depth***
E6	Dense gravelly silty SAND, overlying light brown SILTSTONE rock	2.89m	1.45m (R) 2.80m (R) 5.55m (R)	Highly weathered, highly fractured, very soft rock. **Significant core loss above 6m**.	Below 6m	8.81m
E7	Medium dense gravelly SILT, overlying light brown to grey TILLITE rock	0.75m	1.50m (R)	Highly weathered, very highly to moderately fractured very soft to soft rock,	Below 15.7m	None
E64	Medium dense GRAVEL with COBBLES, overlying dark olive TILLITE rock	0.62m	-	Moderately weathered, very highly to moderately fractured, hard rock	Below 0.62m	22.11m
E100	Medium dense silty GRAVEL, overlying red-orange to black SHALE	1.67m	-	Highly weathered, highly to very highly fractured, very soft rock	Soft rock below 16.6m	16.85m
W411	Dense silty gravelly SAND, overlying dark grey TILLITE	1.58m	1.55m (R)	Highly weathered, highly to very highly fractured, soft to medium hard rock. **Core loss above 8m.**	Below 4.5m	26.27m
W417	Dense gravelly CALCAREOUS SILT with COBBLES, overlying dark olive SILTSTONE	**10.73m**	2.20m (R) 3.80m (R)	Highly weathered, very highly to moderately fractured, soft rock. **Significant core loss above 11m**.	Below 18.7m	23.83m
W452	Dense gravelly silty SAND, overlying dark olive to grey SANDSTONE	0.95m	-	Moderately to slightly weathered, highly to slightly fractured, medium hard to hard rock	Below 0.95m	16.54m
W521	Medium dense clayey GRAVEL, overlying dark grey SILTSTONE	0.45m	-	Highly weathered, very highly fractured, soft to medium hard rock	Below 1.5m	26.05m
W564	Medium dense silty sandy GRAVEL with sporadic BOULDERS, overlying dark olive TILLITE	2.00m	-	Highly to moderately weathered, very highly fractured, soft to medium hard rock	Below 6.8m	19.20m

R = Refusal of SPT in excessively dense substrate / cobbles

The measured orientation of bedding planes varies between horizontal to ~45° (compare E100 to W521). Dominant joint orientation varies from subvertical to ~45°. Joints tend to be narrow to wide, rough to slightly rough, and stained with minimal clay infill, indicating a partial opening of the joint structures. Drawing a correlation for continuity between strata is problematic across such marked distances as between boreholes at Choje WF, as demonstrated by the illustrative cross-section depicted in Figures 13 and 14 overleaf, showing the Western and Eastern block borehole sections respectively. The variation in rock type

and condition is a function to the inclined nature of regional strata in the area, which dips away from the horizontal. It is also a function of the depositional history of the sedimentary strata, showing repeating cycles of sandstone and mudstone with then regional metamorphism altering to shale and quartzitic sandstones. The glacial actions and deposition of tillite equally have affected this strata distribution. Lastly, the variation is a function of localized topography and ensuing chemical alteration at each borehole position.

W564A	-	350	-	600	950	Yes
W564B	-	350	-	350	700	Yes

As may be noted, the majority of trial pits excavated across the site presented early refusal of the TLB at depths shallower than the anticipated 3.0m below existing ground level. This is symptomatic of the density of the colluvial, alluvial and residual soils across the site, enhanced by the dry conditions and frequency of cobbles and calcification (magnesium and ferric ion deposition as calcrete) in the profile.

The soil profile observed in shallow test pits on the site is quite variable in terms of particle sizes, but is typically dominated by coarse, granular soils with a significant amount of silt-sized fines (i.e. silty gravelly sand and silty sandy gravel). The soil cover recorded in test pits is generally thin (<2m), with localised thick accumulations of transported alluvium occurring along or adjacent to natural drainage lines, most notably at WTG W417 where soil cover extends to a depth of 10.7m. Localised, but significantly thick deposits of high-

level terrace gravel were encountered at the 400MTS substation (refer to soil profile MTS2, Appendix C).

Results of the DCP testing illustrated a picture of generally competent soil conditions for lightly loaded structures at shallow depths across the site. DCPs mostly refused within 1.0m of surface, with many refusing within the upper 0.5m. Refusal was broadly due to dense soil conditions, as well as the presence of cobbles in the profile, which are widespread throughout the transported and residual soils on the Choje site. Pedogenic accumulation of ions and the ensuing calcification of the profile is also widespread in arid conditions such as these, and further "weakly cements" the soil profile, leading to increased density and resistance to the DCP probe.

The results of all DCPs are plotted in Chart 5.1 and demonstrate the general trend of "dense" soil types across the site.

5.2 Laboratory Test Results

Laboratory test results herewith presented are as retrieved from borehole soil and cores, trial pits and groundwater standpipes. All samples may be classified as *disturbed* samples, as Shelby tube sampling within boreholes was unsuccessful due to high soil density.

5.2.1 Grading and Atterberg Limits

Representative soil samples were collected from test pits and borehole core for grading, Atterberg limits and moisture content tests (foundation indicator) to determine the index properties of the insitu soils and classify the soil types according to the Universal Soil Classification (USC) system. The results of the tests are shown in Table 5.3.

The lab results indicate that the soils are dominated by silty sands and silty gravels, with low clay content (generally <10% clay) and low to medium plasticity of fines (PI max 28, but PI of whole sample <15). Potential expansivity according to the Van der Merwe method (Van der Merwe, 1964) is low in all test samples.

5.2.2 Soil Density and Strength Tests

Representative soil samples were collected for modified AASHTO density, CBR and indicator tests to determine the compaction/strength relationship and potential as natural construction material for use in earthworks and road pavements. The results of the tests are summarised in Table 5.4.

The test results indicate sporadic sources of potentially useful natural materials (G5-G7 quality in terms of the TRH14 classification system) for earthworks and road-building purposes, but the several of the tests indicate moderate plasticity and low CBR values, the combined effect of which reduces the quality of the materials to G9 or G10. The tests also indicate that the *in-situ* soils tend to be slippery in wet conditions and dusty in dry conditions, with corrugations becoming a maintenance problem. Plasticity and grading are important in the selection of suitable materials for gravel wearing course on access roads.

Recommendations for material usage are given in the following section of this report.

5.2.3 Rock Strength Tests

Selected samples of intact rock core were collected from foundation influence zones (2 – 4m below existing ground level) in boreholes for Uniaxial Compressive Strength (UCS) tests to determine rock strength and estimate bearing capacity for turbine foundations. The results of the tests are summarised in Table 4.

The tests indicate low UCS values for the weakly cemented calcrete soil at W417 (2.9MPa). The highly

weathered tillite at E7 also displayed relatively low UCS values (9.2MPa) as expected, when compared to the harder, moderately weathered tillite from E64 (50-63MPa). The sandstone from W452 displayed very high UCS values (70-106MPa).

In general, the tests indicate the highly variable strength of the different rock types, with some potentially low UCS values which will have to be factored in to the final foundation design. All tested rock showed, however, UCS values in excess of 2MPa.

Table 5-5: UCS Strength Test Results

BH No	*Depth (m)*	*Strength (MPa)*	*Failure Type*
E7	2.78-3.12	9.2	Shattered
E7	3.17-3.45	29.2	Sheared
E64	1.60-1.87	63.8	Sheared
E64	2.31-2.58	50.0	Shattered
W411	4.93-5.05	14.1	Sheared
W411	7.80-7.93	43.0	Sheared
W417	6.64-6.76	2.9	Shattered
W417	7.43-7.57	2.9	Shattered
W417	10.73-10.93	41.4	Sheared
W452	2.46-2.65	70.8	Shattered
W452	2.65-2.85	106.7	Shattered
W521	2.27-2.46	13.2	Shattered
W521	2.71-2.95	9.6	Shattered
W564	4.96-5.10	27.7	Shattered
W564	6.60-6.72	78.6	Shattered

Selected samples of fragmented rock core were also collected from similar foundation influence zones in borehole cores and subjected to point load strength index (PLT) tests to estimate rock strength and estimate bearing capacity for turbine foundations. The results of the tests are summarised in Table 5.6.

Several of the samples were recorded by the laboratory as fracturing as the test commenced and returned no meaningful results, but several other samples produced results ranging from I_s = 0.2 to 9.1, which roughly correlates to UCS of 4-180MPa. Again, the tests indicate the soft nature of some of the rocks, specifically the shale from E6 and E100 and weathered tillite from E7, and the relatively hard tillite from E64 and W411 and sandstone from W452.

5.2.4 Soil and Groundwater Chemistry Results

Representative samples of various soil types were collected for pH and electrical conductivity (EC) to determine the potential aggressiveness (corrosivity) of the soil towards buried structures and underground electrical services. The results of the tests are summarised in Table 5.7.

Table 5-7: Soil corrosivity tests results

TP No	*Sample Depth(mm)*	*pH*	*EC µS/m*
E6A	400-2100	8.09	846

W521B	100-350	7.60	225
W564A	350-900	7.98	250
W564B	350-700	8.00	241

The tests indicate slightly elevated pH levels (alkaline conditions) with sporadic moderate conductivity in some tests, indicating potentially corrosive conditions towards buried metals. The exception being at position WTG E64 and in the vicinity of the Eastern Block proposed substation site, where slightly acidic soils were encountered.

In addition to the soil tests, groundwater samples were also collected from installed standpipes in several boreholes for pH and Electrical Conductivity (EC) tests to determine the corrosivity (acidity and salinity) of groundwater against buried structures and services. This was conducted even though the depth to the groundwater table currently exceeds 8m below natural ground level and would have little effect of foundations, as testing occurred during winter. Seasonal fluctuations of the groundwater table may still result in an upwards movement of the resting groundwater level and proximity to foundations after rainfall events. The results of the tests are summarised in Table 5.8 overleaf.

Table 5-8: Groundwater chemistry tests results

BH No	*Depth of water table (m)*	*pH*	*EC mS/m*
E6	8.81	7.2	101
E7	-	-	-
E64	22.11	6.9	106
E100	16.85	7.3	101
W411	26.27	*	*
W417	23.83	*	*
W452	16.54	8.7	48
W521	26.05	*	*
W564	19.20	8.1	223

The test results indicate slightly elevated pH levels (alkaline) in some samples combined with brackish/slightly saline groundwater quality. The results indicate fairly high dissolved salts (mainly Cl^-), with TDS estimated at 6.7xEC (mS/m). Brackish water can be highly corrosive towards exposed metallic structures and steel reinforcement, requiring adequate concrete cover or polymeric coating.

BS EN1008 does not recommend such water for use in the making of steel-reinforced concrete, nor direct exposure of groundwater towards concrete structures as it registers as being slightly corrosive (chemical environment classified as XA1 in terms of BS EN 206-1). COTO (2018) specifies the maximum EC of water for use in general earthworks and layerworks compaction is 150mS/m. This needs to be accounted for in the final foundation and site structural design.

6 GEOTECHNICAL SITE ASSESSMENT AND RECOMMENDATIONS

The assessment of ground conditions for the establishment of a utility-scale wind farm is a complex and detailed undertaking. The dynamic nature of a turbine necessitates review of a wide variety of geotechnical aspects, including bearing capacity, seismic influences, gapping, overturning, settlement, subgrade reactions, excavatability and buoyancy. Whilst these aspects are taken in to consideration during the Preliminary Geotechnical Study, the early stage of the sequencing of the study does not allow for detailed geotechnical design parameters to yet be isolated for each turbine position. The positions will also in all likelihood, shift somewhat as final layout alterations ensue. The focus of this study is therefore not to provide design calculations for effective foundations, but rather to present the results of the geotechnical information retrieved to date and the general foundation considerations that will apply to the site development.

The Choje site is generally located in a stable geological environment, without the presence of dolomitic risk of sinkholes, active fault lines or notable seismicity. The near-surface rock conditions over much of the site will allow for shifts of turbine positions to made where they lie in localised poor founding. This will

necessitate a detailed geotechnical study to be conducted in order to clearly isolate the most economical founding positions as early as possible.

6.1 Turbine Foundations

As has been discussed in earlier sections of this report, the rockhead contact lies at a relatively shallow depth across most of the site. Wind turbine positions are naturally selected in elevated terrain, and thus these are usually in areas of rock outcrop near to surface. With the wide area selected for the Choje project, however, it is inevitable that some positions will be positioned in floodplains and side slopes, with deeper soil cover. Readers are referred to PP225941-ZACT-R-01-A Choje Wind Farm Desktop Report for a description of the prevailing founding classes on the Choje site.

Review of the 9 borehole profiles indicate the majority as providing bearing on suitable rock types close to surface. Whilst no final selection of turbine model has been made for the Choje site at the time of drafting of this report, and therefore no foundation loadings are available, it may be assumed that a bearing capacity of at least 300kPa will be required, but probably higher than this for the high hub height turbines under contention. "Very soft rock" varies in bearing capacity from 200-400kPa, with a Factor of Safety, whilst "soft rock" may range from 400-950kPa. These values are, however, highly variable and dependent upon structural elements prevailing at the site – very soft rock may still provide sufficient bearing for the turbine, provided the base is designed with a footing broad enough to suit.

The RQD readings for some of the positions with shallow rock still show low values of rock quality in the 3m-below-ground-level range (see W411 and W564). This may be ascribed to the high degree of fracturing of notably the tillite and shales. This is a factor to account for, however may also be factored into a suitable design as there will be confining pressure on the in-situ material below the foundation from the surrounding country rock. Therefore, even though the rock is highly fractured, it could potentially still provide adequate founding. The exception may be in areas of high groundwater table, where a fractured substrate could allow for hydraulic "pumping" under the dynamic load fluctuations of the turbine. This could serve to degrade the foundation base. The deep groundwater table in the area, however, suggests this would be unlikely.

For founding at positions of shallow rock head contact, a standard shallow gravity foundation is predicted as being suitable. Embedment depth would be at least 3m it is anticipated, which will require hard excavation at a number of the positions, either through the use of an excavator-fitted rock pecker, or through directional blasting. Footing design in rock should account for the impermeable nature of the substrate and make allowance for buoyancy.

Boreholes E6 and W417 demonstrated ground conditions that are less favourable and would therefore call for an adapted design. E6 displayed sandy cover to just under 3m and then highly to completely weathered, very soft rock with almost total core loss to 6.0m, associated with its position in a non-perennial drainage line and the resultant alluvial deposition. W417 showed highly weather calcareous silt (poorly formed calcrete) in excess of 10m depth, which is problematic from a weak cementation of grains and potential collapsibility point of view. It is also indicative of "pseudo-karst" features prevailing in the area, where calcrete formation may allow for the presence of small voids in the profile. It such positions the turn=bines should potentially be relocated to nearby sites of more favourable founding. Where relocation is not possible, the foundation design will need to be adapted to suit, as well as the in-situ bed preparation prior to the casting of the base. Ground improvement techniques may here be considered, such as dynamic compaction.

The foundation should be over-excavated, and an improved engineered soil raft be constructed. The soil raft should make use of a minimum of G5 – G3 aggregate quality imported material, deposited in maximum of 200mm layers and compacted from 95% to 98% MDD, above which the gravity footing may be commenced. The depth of the improved soil raft will be a function of the final WTG footing size, and its ensuing pressure bulb's zone of influence.

The position E100 demonstrated very soft rock and RQD readings of "0" for much of its upper extent. Where potentially compressible substrate is located 3-5m below surface, engineered soil rafts are usually considered. It is therefore deemed to be a borderline position, which may or may not require an adapted design with improved soil raft. Dynamic compaction would be deemed unsuitable at this position. Further investigatory techniques, such as the dynamic probing super-heavy and geophysics utilised during the detailed geotechnical investigation, would assist in developing the design for this position further.

An alternative solution for turbines located in deep soil cover may also involve piling. The merits of piling at each position are dependent upon the shear friction that may be expected from the surrounding substrate, and the depth to a competent terminating horizon.

For gravity foundations on slopes, the distance between the edge of the foundation and the slope face (measured horizontally at the foundation level) should ideally be not less than 1x the diameter of the foundation. Furthermore, turbine foundations should ideally not be located on slopes which exceed 18°.

Turbine positions located within the 1:100-year floodline should be relocated wherever possible to higher ground. The Somerset-East area is well-known for the potential occurrences of flash-flooding, which may cause significant erosional forces and foundation undermining, should it reach turbine positions.

6.2 Crane Platforms and Access Roads

Trial pits excavated at turbine positions were used to estimate the material properties and depth of cover, whilst DCP testing was conducted in order to inform on soil densities in the area. The results show a dense soil cover generally across the area, widely inculcated with calcrete deposition to varying degrees. Cobbles and boulders are frequent in the upper profile. Clay percentages are mostly low, with heave not anticipated to be a developmental concern. Most DCPs refused close to surface, on dense soils or cobbles. Crane pads are therefore judged to be constructed in the standard manner. Development of the crane platform should proceed with the topsoil being retrieved to a depth of 300mm or hard rock, and stockpiled for later landscaping use. A mixture of soil and rock material excavated from road box cuts and lay down areas may then be used for bulk filling on platforms (cut to fill platforms), provided it meets the minimum specifications (recommended minimum G9 for bulk fill on platforms, compacted to 93% MDD, rockfill, compacted to 8 roller passes). Layers of imported G5 material should then comprise the upper layers, placed in 200mm increments and compacted to 95% MDD at OMC.

The site topography will exert a significant control over the access road layout. Consideration should be given to existing access roads and stream crossings to minimise impacts of earthworks on the site.

Allowance should be made for hard excavations in road box cuts and lay down areas on sloping terrain. Bulk fill materials should be adequately benched into the *in-situ* sloping ground to prevent sliding of the wedge of fill material. The maximum safe slope of permanent road fill embankments is 1v:2h. Pipe or box culverts will

be required to cross dry riverbeds and streams, and this will require environmental consideration. Adequate camber and side drains should be accommodated in the design of internal access roads to ensure accessibility during peak rainfall events. Access road design widths for blade transport is usually 4.5-6m, as designed by the project pavement engineer. Subsoil drains along roads are not envisaged but may be considered along major access routes.

6.3 Slope Stability

The site topography is characterised by hilly terrain with some steep slopes. The steep hills and ridges are typically underlain by shallow, relatively stable rock formation and global stability problems are unusual. Local stability problems may be encountered adjacent to natural drainage lines where soil cover is typically thicker and stream embankments may be eroded and undermined during peak flood events.

No cuttings were investigated as part of this initial geotechnical study. Any proposed access road cuts in excess of 5m should be drilled as part of the detailed study in order to review the stability and inform on the most appropriate angle of inclination. The Cape and Karoo sediments in the area are relatively horizontal in dip in the low-lying areas, however this changes to near-verticle dipping angles close to ridegelines. Tillite is highly variable in not only composition and weathering, but dip angle as well and should be treated with caution when designing cuttings.

Small portions of the site are also crossed by Jurassic-age dolerite dykes. These form longitudinal ridges that are very resistant to weathering and erosion, as a result of dolerite's high strength and durability. Aggressive blasting may be required to remove unweathered dolerite where access roads are aligned through a ridge.

6.4 Site Structures

The proposed position of the substation in the Eastern Block showed shallow rock conditions, with no trial pit progressing deeper that 0.6m below current ground level. All samples showed silt, sand and gravel, with low activity values bar a single sample from trial pit SS4 between 0.2-0.45m depth which showed a linear shrinkage value of 10. LS values in excess of 8 may be prone to moisture-related shrinkage and lead to cracking of overhead structures. Owing to the shallow depth to rock however, this is not viewed as a significant concern. Structures should proceed on standard strip footings, placed upon medium hard rock at 0.4-0.6m.

The proposed position of the 400MTS in the Western Block showed variability of soil cover. Most trial pits refused at a shallow depth of 0.7m, however one pit proceeded to 2.9m depth without refusing. This may indicate that the three other pits refused on boulders in the profile, and actual rockhead depth is in excess of 3m, or alternatively that the 2.9m pit was positioned over a cavity or rock contact depression. It is recommended that additional pits are excavated at this position prior to foundation design.

All vegetation must be cleared from the areas over which any structures are to be constructed. Furthermore, the upper 200 mm of topsoil must be removed and stockpiled for later use in landscaping / rehabilitation. Cavities remaining in the soil profile must be refilled with a suitable cement-like fill material and re-compacted to a similar density as the surrounding soils.

6.5 Excavatability

Section 4 of this report detailed excavatability conditions that may be expected along the access road routes and provided guidelines for excavation classes. Earthworks and excavations at the turbine positions themselves are likely to encounter bedrock and/or boulders which require special consideration in terms of excavatability. Hard excavations, requiring blasting or wedging and splitting are likely to be encountered at depths beyond 1m in many parts of this site.

Table 6.1 overleaf reflects the estimated excavation conditions that may be expected at the nine drilled turbine positions and is based upon the SABS 1200D (1988) excavation classes. Maximum expected founding depth of 5m has been assumed, with conditions divided into reaches of 0-1m, 1-3m and 3-5m depths.

Table 6-1: Borehole excavatability estimations

PREDICTED EXCAVABILITY CONDITIONS			
Position	Depth (m)		
	0.0 - 1.0m	1.0 - 3.0m	3.0 - 5.0m

WTG W521	**S-I**	**H**	**H**
WTG W564	**S**	**A-H**	**H**

S - Soft Excavation

I - Intermediate Excavation

H - Hard Rock Excavation

A - Boulder Class A

B - Boulder Class B

Challenging rocky outcrops presenting obstacles to access roads and level platforms may be expected where positions are located on slopes. Neat excavations are generally not expected possible for many of the Choje positions, with a significant amount of overbreak anticipated along trenches.

Maximum slope angles for temporary excavations for turbine foundations and cable trenches are 1v:0.5h in rock and 1v:1h in soil. Temporary lateral support measures may be required where deep excavations are anticipated.

6.6 Use of on-site materials

Preliminary laboratory testing has shown that multiple sources of good construction material persist across the site, particularly where hard rock is located close to surface. As such positions a single or multi-stage crusher may be deployed to service a few nearby turbine positions and be calibrated to produce selected and subbase grade materials.

Several borrow pits are located across the Choje site, most of which are developed by the Department of Roads & Transport. These BPs are currently the source of a separate licencing study being undertaken, however indicate a good availability of G5-G7 grade natural gravels.

Potential may also exist for good quality concrete and bedding sand in alluvial courses on the site, such as near to position E6. These should be explored in greater detailed by way of trial pits and channel sampling during further studies.

Caution should be extended to the use of Karoo mudrock on the site. Such strata, identifiable by their purple and olive-green varietals, appear moderately weathered and medium hard upon excavation, however rapidly degrade in the presence of exposure to air and the absorption of water vapour into the clay particle interlays of the rock. This results in particle expansion and degradation of the material to a completely weathered state in a few weeks. Should mudstone be utilised on access roads at Choje, it is suggested to be added as a binder material to a coarser particle mix. Alternatively, the material may be excavated and emplaced into the road prism and then quickly covered by successive pavement layers, before degradation takes place.

Naturally occurring hardpan calcrete is also widely occurring across the site, although wasn't specifically targeted or sampled during the course of this study. Calcrete in its well-formed state often occurs as an upper crustal surface phenomenon, and therefore is unlikely to be deposited in thicknesses deeper than 1-2m, however is widespread and may yield quality in the G5-G7 range. Where it has been further weathered, it may develop a higher PI and then could also be used as a binder material to hard-crushed aggregate.

The use of hard rock as concrete aggregate is yet to be explored at the Choje site. A commercial quarry located in the Western Block (*Irhafu Middleton Quarry*) currently provides multiple grades of good quality dolerite, which will serve as an acceptable concrete aggregate. For development of the projects in the Eastern Block the economic viability of transport from this commercial quarry to the site will need to be assessed. Should it prove too costly, then a new aggregate source in the Eastern Block should be developed. Initial reconnaissance indicates that potential hard sandstone is available, as well as possibly unweathered tillite. Both sources would require drilling and sampling. The testing of tillite would need to include thin-section analysis for deleterious minerals, as clast inclusions sometimes have the propensity for alteration to clay-minerals with time.

6.7 Site Drainage

The Choje site is cross by a great number of non-perennial drainage lines, as well as permanent river bodies. As mentioned previously, the site is arid with a low rainfall - 683mm per annuum recorded for Grahamstown (Climate-Data.org, 2019). The site is also traversed by the Department of Water Affairs administered irrigation canal.

Drainage lines are subject to rapid flash-flooding and erosion after heavy precipitation events. Caution must therefore be assumed in the stream protection of stream routes around working areas on the site, as well as turbines bases and crane platforms. The use of gabions and reno mattresses is advised for anti-erosional measures.

The groundwater table was measured in all boreholes and found to lie beyond the current depth of influence of turbine foundations. Quarterly inspections of the groundwater table in boreholes will be conducted over the next 12 months as an ongoing monitoring programme. This report may also be read in conjunction with

the DNV GL subcontracting geohydrologist's report "*Desktop Groundwater Feasibility Assessment for Choje Windfarm Projects, Eastern Cape",* and referenced 005020R01.

6.8 Further Studies Required

This report represents the findings of a preliminary geotechnical study, performed to obtain initial ground data on the site as a whole. Prior to finalisation of design, a detailed geotechnical study will need to be performed. As a minimum, this should include the following:

- Rotary core drilling of each proposed foundation position to a depth not less than 1.5B, where B = diameter of the proposed WTG foundation footing. Sampling and logging of all trial pits according to South African standards by a professional engineering geologist;
- Excavation of trial pits for bulk material sampling at each turbine position, as well as nearby crane platform positions. Sampling and logging of all trial pits according to South African standards by a Professional Engineering Geologist;
- Excavation of trial pits for bulk material sampling along access road routes. Trial pit frequency of a minimum of 1km intervals, staggered on alternating sides of the centreline, is advised. Sampling and logging of all trial pits according to South African standards by a Professional Engineering Geologist;
- Retrieval of samples of rock core, disturbed and undisturbed soil and water samples for laboratory analysis. Advanced geotechnical testing;
- Evaluation of subsurface density conditions through the use of DCP and DPSH testing at turbine, road access and structural positions as directed;
- Retrieval of p- and s-wave ground propagation data through the use of CSW and MASW geophysics tests. It is advised to utilise both forms of testing on the site, as CSW may provide better information in the near-surface environment, however MASW will be more effective in the harder rock and deeper penetration of the Karoo and Cape formations;
- *In-situ* electrical resistivity testing at substation positions and selected turbines;
- *In-situ* thermal resistivity testing at selected positions along primary cable routes;
- Further material sources reconnaissance studies as required for hard rock aggregate in the Eastern Block;
- Production of a detailed geotechnical investigation report for each sub-windfarm site detailing all required geotechnical parameters for effective WTG foundation design, as well as cable routes, access roads
- Confirmation of geotechnical conditions expected at each turbine location by a professional engineering geologist or geotechnical engineer during construction. Inspections to be performed after excavation of turbine bases, prior to foundation casting to identify any soft spots, unexpected structural variations or groundwater fissures.

7 CONCLUSION

DNV GL has conducted a preliminary geotechnical investigation for the proposed development of a cluster of utility-scale wind farms between Grahamstown and Somerset East, Eastern Cape. The site was investigated by rotary core drilling, trial pitting, in-situ density testing as well as laboratory soil and groundwater testing.

The site has been found to be favourable for the development of wind turbine generators and associated civil roads and structures. Colluvium, alluvium, residual soils, mudstone, siltstone, tillite and sandstone characterised the trial pit profiles and borehole logs across the investigation site. Comment on the excavatability of the material has been provided for the proposed access roads and turbine positions. It is envisaged that hard excavation techniques will predominantly be required across the site due to the shallow depth to rock encountered, but that in an estimated 30% of positions softer ground conditions may prevail.

A required bearing capacity and founding depth was not provided for the site, as turbine selection is still ongoing. It is estimated, however, that a bearing capacity of approximately 300 kPa is available at a depth of 2-3 m across most of the site, except at a lesser number of weathered positions where an adapted foundation design will be required in the form of ground improvement and engineered soil rafts.

Buoyancy conditions may occur at positions in hard rock after heavy rainfall events, where surface drainage has not been adequately designed to prevent water ingress to the foundation excavation. In other positions, however, the deep water table would negate the threat of buoyancy.

Assessment of the rotational stiffness is dependent on the stiffness limits placed on the design by the turbine manufacturer. These have not yet been assessed for the site or a specific turbine model.

The extent of the investigations undertaken is deemed adequate, within the time and budget constraints, to present an overview of the geotechnical conditions across the investigation site.

It must be borne in mind that the overall interpretation of geotechnical conditions is based upon point information derived from the respective test positions and that conditions intermediate to these have been inferred by interpolation, extrapolation and professional judgement. The interpretation of the geotechnical conditions is based on information available at the time of drafting this report by DNV GL South Africa and it's partners.

Technical Signatory

1. The opinion column is an interpretation of the direct comparison between the quoted specification and the single test sample results obtained. The compliant (✓), non compliant (×) and uncertain (∗) opinion indicators are based on an approximate 95% level of confidence with reference to SAMM GUIDANCE 1, Issue 2 : 20 June 2007 Section 2.
2. The uncertain (∗) indicates that the test result is either equal to or is above / below the specified limit by a margin less than the measurement uncertainty; it is therefore not possible to state compliant (✓) or non compliant (×) based on a 95% level of confidence with reference to SAMM GUIDANCE 1, Issue 2 : 20 June 2007 Section 2.
3. This report (with attachments) is the correct record of all measurements made, and may not be reproduced other than with full written approval from the Technical Director of Outeniqua Lab EC cc.
4. Measuring Equipment, traceable to National Standards is used where applicable. Results reported in this Test Report relate only to the items tested and are an indication only of the sample provided and/or taken.
5. While every care is taken to ensure the correctness of all tests and reports, neither Outeniqua Lab nor its employees shall be liable in any way whatever for any error made in the execution or reporting of tests or any erroneous conclusions drawn therefrom or for any consequence thereof.

Technical Signatory

1. The opinion column is an interpretation of the direct comparison between the quoted specification and the single test sample results obtained. The compliant (✓), non compliant (×) and uncertain (∗) opinion indicators are based on an approximate 95% level of confidence with reference to SAMM GUIDANCE 1, Issue 2 : 20 June 2007 Section 2.
2. The uncertain (∗) indicates that the test result is either equal to or is above / below the specified limit by a margin less than the measurement uncertainty; it is therefore not possible to state compliant (✓) or non compliant (×) based on a 95% level of confidence with reference to SAMM GUIDANCE 1, Issue 2 : 20 June 2007 Section 2.
3. This report (with attachments) is the correct record of all measurements made, and may not be reproduced other than with full written approval from the Technical Director of Outeniqua Lab EC cc.
4. Measuring Equipment, traceable to National Standards is used where applicable. Results reported in this Test Report relate only to the items tested and are an indication only of the sample provided and/or taken.
5. While every care is taken to ensure the correctness of all tests and reports, neither Outeniqua Lab nor its employees shall be liable in any way whatever for any error made in the execution or reporting of tests or any erroneous conclusions drawn therefrom or for any consequence thereof.

- **Specimens delivered to Outeniqua Lab in good order.**

L Malgraff (Member)
For Outeniqua Lab EC cc.
Technical Signatory

1. The opinion column is an interpretation of the direct comparison between the quoted specification and the single test sample results obtained. The compliant (✓), non compliant (×) and uncertain (∗) opinion indicators are based on an approximate 95% level of confidence with reference to SAMM GUIDANCE 1, Issue 2 : 20 June 2007 Section 2.
2. The uncertain (∗) indicates that the test result is either equal to or is above / below the specified limit by a margin less than the measurement uncertainty; it is therefore not possible to state compliant (✓) or non compliant (×) based on a 95% level of confidence with reference to SAMM GUIDANCE 1, Issue 2 : 20 June 2007 Section 2.
3. This report (with attachments) is the correct record of all measurements made, and may not be reproduced other than with full written approval from the Technical Director of Outeniqua Lab EC cc.
4. Measuring Equipment, traceable to National Standards is used where applicable. Results reported in this Test Report relate only to the items tested and are an indication only of the sample provided and/or taken.
5. While every care is taken to ensure the correctness of all tests and reports, neither Outeniqua Lab nor its employees shall be liable in any way whatever for any error made in the execution or reporting of tests or any erroneous conclusions drawn therefrom or for any consequence thereof.

About DNV GL

Driven by our purpose of safeguarding life, property and the environment, DNV GL enables organizations to advance the safety and sustainability of their business. We provide classification, technical assurance, software and independent expert advisory services to the maritime, oil & gas and energy industries. We also provide certification services to customers across a wide range of industries. Combining leading technical and operational expertise, risk methodology and in-depth industry knowledge, we empower our customers' decisions and actions with trust and confidence. We continuously invest in research and collaborative innovation to provide customers and society with operational and technological foresight. Operating in more than 100 countries, our professionals are dedicated to helping customers make the world safer, smarter and greener.
