ABSTRACT

The purpose of this study is to determine the provenance of Middle Stone Age lithics, and the procurement strategies employed to obtain them, at Olieboomspoort Rock Shelter (OBP) and Mwulu's Cave. Macroscopic (and stereomicroscopic) analysis, portable X-ray fluorescence, thin section petrography, and Inductive Coupled Plasma Mass Spectrometry are used to achieve this purpose by identifying and comparing the lithics to the geological samples collected from formations around the sites. Quartzite, shale, sandstone, dolerite and quartz lithic raw materials from OBP may have been procured from the Mogalakwena Formation locally and non-locally although the provenance of chert lithics remains unknown. At Mwulu's Cave, quartzite and quartz lithics were possibly made from raw materials procured from local outcrops in the Black Reef Quartzite Formation (BRQF) and chert lithics were possibly made from local or semi-local BRQF raw materials. Duitschland Formation shale raw materials may have been procured semi-locally from Mwulu's Cave. These are preliminary hypotheses on the provenance and procurement of lithics at these sites and more petrography and ICP-MS analyses need to be conducted to verify them.

ACKNOWLEDGEMENTS

I am very grateful to my supervisors Dr Paloma de la Peña Alonso, Dr Zubair Jinnah, and Dr Guilhem Mauran for all advice they have given me and their guidance. Thank you for all the hours you put into correcting my dissertation and ensuring its quality. I have learned so much from being under your supervision.

I would like to thank Dr Tebogo Makhubela from the Department of Geology at the University of Johannesburg for lending me the portable X-ray fluorescence instrument for the analysis of my samples.

I am also grateful that he, Ms Dakalo Maphanda, Mr Tumelo Molefyane, Mr Mathabela Tsikoane, Mr Maropeng Mpete, and Mr Dirk van Rooyen assisted me on my prospection survey around Olieboomspoort Rock Shelter. Thank you to Mr Wim Biemon too, for his hospitality.

My gratitude goes to Mr Caiphas Majola and Mr Sam Tshabalala at the School of Geosciences for helping me prepare my samples for thin section and ICP-MS analysis, and for producing the thin sections. I also thank Mr Marlin Patchappa for running the ICP-MS analysis on my samples.

I am thankful to the Palaeontological Scientific Trust (PAST) and the National Research Foundation (NRF)/Genus for funding my project. I could not have done this without your financial aid.

Lastly, I would like to thank my loved ones for their faith, patience, and support. Thank you for driving me to constantly be the best version of myself that I can be.

Dedicated to my parents

Maud and Cry Masia

1 INTRODUCTION

This project investigates the relationship between archaeological lithics and geological outcrops around two sites. I aim to determine the provenance of the lithics through raw material analysis in order to question past populations' procurement strategies. The lithics belong to the Middle Stone Age layers at Olieboomspoort Rock Shelter (OBP, Limpopo) and Mwulu's Cave (Limpopo). These sites have chronologies associated with Marine Isotope Stage 6 and 5, respectively, with OBP dated around 150 ka (Val *et al*., 2021) and Mwulu's Cave around 90 ka (Feathers *et al*., 2020). The study areas include outcrops and geological sources within a 30 km distance from OBP and those within a 12 km distance from Mwulu's Cave. To identify the rock types of the lithics and the outcrop samples, petrography and geochemical analyses are applied. From these results, comparisons between lithic and outcrop samples are made in order to determine procurement strategies.

1.1 The Middle Stone Age

The Middle Stone Age (MSA), as defined by Goodwin and van Riet Lowe (1929), is a cultural phase spanning 300 ka to about 40-20 ka (Wadley, 2015). This phase is contemporaneous with a diverse population of hominins in Africa, from archaic species to *Homo sapiens* (Berger *et al*., 2017). South African fossil examples of these species include *Homo naledi* fossils from the Rising Star cave system (335-236 ka; Berger *et al*., 2015) and other hominin artefacts such as a mandible and radius from Cave of Hearths (500-200 ka; Tobias, 1971); a tibia and teeth from Hoedjiespunt (300-200 ka; Buck and Stringer, 2014), and more than 50 remains from Klasies River Main Site (110-80 ka; Rightmire *et al*., 2006; Grine, 2012).

During the MSA, particularly during MIS 5, hominins learned to use and control fire (Schmidt *et al*., 2015), and they transported lithics over vast distances (Porraz *et al*., 2013). This means that they knowingly sourced specific raw materials (Porraz *et al*., 2013) and possessed complex cognition (Wadley, 2013). They had the ability to make natural objects cultural (Val *et al*., 2020) and interacted in social networks across

regions (Soriano *et al*., 2015). According to Porraz *et al*. (2020), these are examples of how new customs emerged independently during this time in southern and northern Africa.

The MSA is represented by the disappearance of large cutting tools, the introduction of prepared core technologies, and the hafting of tools (using compound points and adhesives) (Wadley *et al*., 2009). These novelties are distributed throughout MSA chronology in South Africa.

This project focuses on lithics from sites that were defined as belonging to the Pietersburg Industry (defined in the 1920s by Paterson (Sampson, 1974)). Some researchers still use this terminology (e.g. Lombard *et al*., 2012; Porraz *et al*., 2015), although recently de la Peña *et al*. (2019) and Val *et al*. (2021) contested its use. The Pietersburg Industry was described as occurring in the interior of South Africa and was characterised by hornfels, quartzite and andesite cores, as well as long bifacial points made from local raw materials (Wadley, 2015). In South Africa, these sites include OBP, Mwulu's Cave, Border Cave (Beaumont, 1978), Bushman Rock Shelter (Mason, 1957), Cave of Hearths (Mason, 1988), Wonderkrater (Backwell *et al*., 2014), Rufus Cave, Rooirand, Kalkbank, Steenbokfontein (Wadley *et al*., 2016), and Koedoesrand (Figure 1.1).

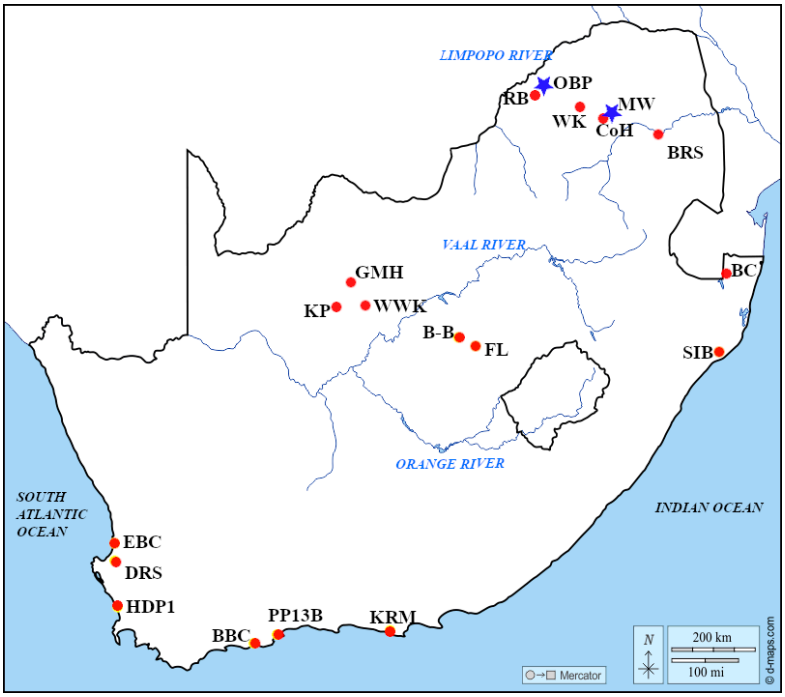

Figure 1.1: Map of South Africa with the locations of Olieboomspoort Rock Shelter and Mwulu's Cave represented by red stars. Other MIS 5 sites indicated by yellow circles include Red Balloon (RB), Wonderwerk (WWK), Elands Bay Cave (EBC), Cave of Hearths (CoH), Bushman Rock Shelter (BRS), Ga-Mohana Hill North Rock Shelter (GMH), Border Cave (BC), Sibudu Cave (SIB), Kathu Pan (KP), Baden-Baden (B-B), Florisbad (FL), Wonderkrater (WK), Klasies River Main site (KRM), Blombos Cave (BBC), Diepkloof Rock Shelter (DRS) and Pinnacle Point Caves (PP13B) (Val *et al*., 2021).

Several technological industries are noted in Africa during the MSA. In South Africa, the transition between the Early Stone Age and the MSA is noted in the Fauresmith Industry (550-300 ka: Chazan, 2015; Wurz, 2013). Examples of sites belonging to this industry include Kathu Pan 1 (Wilkins, 2013) and Wonderwerk Cave (Chazan, 2015). According to Chazan (2015), the Fauresmith is recognised through blades produced from prepared cores and small, rounded bifacial lithics. The Sangoan Industry (242-204 ka) is another old technological industry that occurs in Africa. It spans from northern Africa to southern Africa (Schmid, 2019) at sites like Sai Island in Sudan (Van Peer *et al*., 2003) and Kudu Koppie in South Africa (Kuman *et al*., 2005). The types of tools associated with this industry are bifacial picks, core-axes, denticulates, scrapers, often produced through *Levallois* technologies (McBrearty, 1988). The Still Bay (109 ka; Tribolo *et al*., 2013) and Howiesons Poort (64.8 to 59.5 ka; Wadley, 2013) are also industries noted in South Africa. These are found at sites like Diepkloof Rock Shelter (Porraz *et al*., 2020) and Sibudu Cave (Schmid, 2019).

Occupations at OBP and Mwulu's Cave have been dated to periods coinciding with MIS 6 and 5 respectively. During this time, hominins in South Africa procured local raw materials for lithic production, used *Levallois* and prepared core methods to produce informal tools such as side scrapers, and denticulates (among other tools) (Schmid *et al*., 2016). The MIS 5 has been proposed by Schmid *et al*. (2016) as the transition from triangular blanks to bifacial- and unifacial points (as seen at Bushman Rock Shelter layer '28 and Border Cave).

In South Africa, another example of an archaeological assemblage recorded coinciding with MIS 6 was found at Bundu Farm dating ~394-144 ka (Lombard *et al*., 2013). MIS 5 archaeological assemblages are recorded at sites like Ysterfontein (±132-128ka).

Many other South African sites belong to either both chronological stages or occur continuously from MIS 6 to 5. Examples include Pinnacle Point (~166-160 ka and ~128-110 ka); Duinfontein (~292-125 ka); Wonderwerk (~182-118 ka); and Border Cave (~171-152 ka and ~91-71 ka) (Lombard *et al*., 2013).

1.2 Raw Material Procurement Analysis

Raw material analysis allows us to understand the choices made by hominins to exploit specific raw materials. Through these analyses, we can connect hominin mobility, technologies, choices and social activities to specific places (Clarkson, 2016). Analysing lithics gives us an idea about the material preferences of the hominins who knapped the tools (McHenry and Torrez, 2018). Through material circulation, we can learn about the social and economic networks that existed between populations. These studies look at what material was sourced, from where it was procured, and what this can tell us about the procurement strategies employed at Prehistoric sites.

Here, raw material analysis is used to understand how MSA populations exploited the geological resources available to them. This is investigated through lithological comparison between lithics and geological outcrops around OBP and Mwulu's Cave. This can be done if exploited raw materials were produced from outcrops that can be distinguished by textural or chemical qualities. Through raw material analysis, lithics provide evidence of material selection and transport.

One of the first studies to investigate raw material procurement focussed on Prehistoric behaviours of hominins in the Mediterranean. It was conducted through a comparative analysis between obsidian lithics and regional obsidian outcrops. This information led them to understand Neolithic trade routes and navigation in the area (Dixon *et al*., 1968).

1.2.1 Lithic raw material procurement analyses in southern Africa

A few raw material procurement studies have been conducted in South Africa. An example of a study that is similar to the current project is one conducted by Porraz *et al.* (2020) at Diepkloof Rock Shelter. Raw material procurement analysis was used by Porraz *et al.* (2020) to question technological innovations and behaviours of hominins in the MSA. This was done through Scanning Electron Microscopy coupled to Energy Dispersive X-ray spectrometry (SEM-EDS), X-ray diffractometry (XRD), and macroscopic analyses to analyse lithics from an MIS 5 unit (unit Lynn) at the site. From macroscopic analyses, they identified the lithic rock types as quartzite, quartz, hornfels and other fine-grained materials (Porraz *et al*., 2020). They also found that, from the ochre assemblage, the shale was procured from a geological bed inside the shelter and that the ferricrete was from an unknown source (Dayet *et al*., 2016). From geochemical analyses, they determined that the main raw materials (quartzite, quartz and silcrete) were sourced less than 10 km from the site whereas the finer-grained materials and hornfels were sourced more than 20 km from the shelter (Porraz *et al*., 2020). Through macroscopic and cortical surface analysis they were able to tell that the material was sourced from alluvial terraces in a secondary context (*ex situ*). This means that the primary procurement strategy of the populations who occupied the site during the MIS 5 involved using material that was locally available (Porraz *et al*., 2020). Another point that they made is that because these raw materials are not found in the older Mike stratigraphic unit (only 2% of them were present) but persist throughout the Still Bay and Howiesons Poort, the change in lithic material preference and transport over vast distances was initiated in the MSA (Porraz *et al*., 2020).

Lithic raw material procurement analysis has also been conducted at other South African MSA sites. Examples of these studies include analyses at sites along the Doring and Olifants Rivers (Mackay *et al*., 2022), at Elands Bay Cave (Schmid *et al*., 2016), and at Hoedjiespunt (Will *et al*., 2013). Recently Mackay *et al*. (2022) analysed whether Still Bay foragers used varying materials to knap bifacial points. They also focussed on whether the foragers travelled far to procure these materials, or if local materials were procured. Sites along the Doring River had lithics made from quartzite and those along the Olifants River were made from silcrete. In the East of the Doring River catchment area interbedded layers of shale, quartzite, and sandstone (Bokkeveld Group) were noted. In the West, conglomerates with quartz, chert, quartzite and sandstone pebbles

(Table Mountain Group) were recorded. Silcrete primary sources were noted in both catchment areas. From this information, they conclude that the quartzite used to make bifacial points at sites around the Doring River was procured from the Bokkeveld Group and that the silcrete could have been sourced from five different primary sources (two in the Doring River catchment area and three in the Olifants River catchment area). Based on their findings, they determined that Still Bay foragers indeed travelled far, more than 60 km, to procure raw materials. MSA populations of these sites also used materials available in the catchment area that they occupied. The current study is similar to that of Mackay *et al*. (2022) although more defining methods such as petrography and geochemistry are used.

A study at Elands Bay Cave was carried out to inform on patterns that characterise early hominin behaviours and organisation (Schmid *et al*., 2016). The cave was formed in the quartzitic sandstones of the Table Mountain Group. Conglomerates from the Table Mountain Group are also present around the site (Schmid *et al*., 2016). The archaeological assemblage at the cave is recorded as being composed of coarse- and fine-grained quartzite, quartz, silcrete, and chert. From field surveys and their technological analysis, they found that the early hominins at Elands Bay Cave primarily procured rocks for lithics around the site (98.7% of these lithics being of quartzite). They collected coarse-grained quartzite from inside the cave and raw materials like fine-grained quartzite (pebbles in the conglomerate) and quartz were procured locally (less than 5 km from the cave) (Schmid *et al*., 2016). Silcrete and chert were probably procured semi-locally (5-20 km from the cave) at the Redelinghuys outcrop. This information tells us that procurement of specific rock types was not prioritised, but they preferred quartzite over the equally available quartz (Schmid *et al*., 2016).

At Hoedjiespunt 1 in the Western Cape (South Africa), a study was conducted to reconstruct early hominin activities (Will *et al*., 2013). One of the objectives of the study was to analyse the MSA lithic assemblage in order to shed light on raw material procurement at the site. The principal raw materials identified in the lithic assemblage included quartz, a porphyritic igneous rock with quartz phenocrysts, calcrete, silcrete, and other rock types which occur less frequently (greywacke, hornfels, granite, cryptocrystalline silicates, sandstone, shale and quartzite) (Will *et al*., 2013). Based on cortical analysis and petrography, they discovered that quartz, calcrete and the

porphyritic igneous raw materials were procured locally from primary (directly from the outcrop; *in situ*) and secondary contexts (from depositional environments, not directly from the outcrop; *ex situ*). Using knowledge on regional geology, they concluded that silcrete and 'other' raw materials were procured non-locally. Silcrete was also discovered to have been procured in primary context based on the presence of a similar cortex on outcrops 10-30 km from the site (Will *et al*., 2013).

Raw material studies in South Africa also focus on ochre provenance. Ochre characterisation and provenance studies have been conducted at Nelson Bay Cave (Bernatchez, 2007), Pinnacle Point 5–6 North (McGrath *et al*., 2022), and Diepkloof Rock Shelter (Dayet *et al*., 2016). These studies have demonstrated that ochre at these sites was mainly collected locally with only a few non-local raw materials of possible high value for past populations being noted.

1.2.2 Other lithic raw procurement analyses

In Africa, raw material procurement analyses have been conducted at Olduvai Gorge (Favreau *et al*., 2020), in the Eastern Turkana basin (Braun *et al*., 2009), in the Olorgesailie basin (Brooks *et al*., 2018), as well as at the White Paintings Shelter in Botswana (Nash *et al*., 2013) among others. Similar to the present project, these studies were conducted to determine provenance and procurement strategies at the abovementioned sites.

Favreau *et al*. (2020) conducted a raw material procurement analysis study in the Olduvai Gorge. The study was aimed at determining whether the geological sources of Stone Age stone tools could be found based on their unique mineralogy. They characterised 62 rock samples from 10 outcrops in the Greater Olduvai region using thin section petrography, Electron Probe Microanalysis, as well as SEM coupled with energy dispersive X-ray fluorescence spectrometry (ED-XRF). Their research proves that mineralogical analysis can be a viable technique to source lithic artefacts. It also shows that outcrops of quartzite can be contrasted from one another. This is possible because close to the Olduvai Gorge some outcrops that look macroscopically similar can be differentiated by specific mineralogical characteristics (Favreau *et al*., 2020). They also

found green quartzite in the Olduvai Gorge. Some of the lithics analysed in this study include those made of green quartzite. The green colour of the quartzite lithics is obtained through fuchsite pigmentation and fuchsite is found in quartzites in a neighbouring region- Naibor Soit Ndogo. This means that some sort of transport must have taken place for that green quartzite to be found as a lithic in the Olduvai Gorge. Either the quartzite was procured in Naibor Soit Ndogo or from an unknown outcrop, or the finished tool was transported to the Olduvai Gorge (Favreau *et al*., 2020).

Braun *et al*. (2009) analysed raw material provenance concerning stone availability in the Koobi Fora Formation (Eastern Turkana basin). They used ED-XRF to analyse the trace elements in Oldowan stone tools (basaltic and pantelleritic flakes) found in the area and their source rocks. They concluded that the early hominins procured rocks for lithics along two major river systems that were active in the area during the Plio-Pleistocene (Braun *et al*., 2009).

A raw material analysis was conducted at early MSA sites in the Olorgesailie basin in southern Kenya (Brooks *et al*., 2018). It was noted that obsidian was used to make archaeological artefacts at BOK (Locality B) sites in the Olorgesailie region. They performed portable X-ray Fluorescence Spectrometry and neutron activation analyses on 688 obsidian artefacts from BOK-2 and BOK-4 to find their provenance. From these analyses, they found that 78% of lithics were made from raw materials procured at seven sources 25-50 km from the BOK sites (Brooks *et al*., 2018).

Nash *et al*. (2013) performed geochemical analyses on MSA waste flakes from the White Paintings Shelter. Major and trace elements of lithics and outcrop samples from around the site were analysed through inductively coupled plasma mass spectrometry (ICP-MS) and inductively coupled plasma atomic emission spectrometry (ICP-AES). From these analyses, it seems that instead of procuring silcrete from the Okavango River and the Xaudum Valley, early hominins travelled over 220 km to collect it from Lake Ngami and the Boteti River south of the Okavango Delta (Nash *et al*., 2013). The hominins at the White Paintings Shelter Used Lake Ngami and the Boteti River silcrete throughout the 50 000 years of MSA occupation at the site. This finding suggests that the Lake Ngami and Boteti River silcrete was preferred. It also suggests that early

hominins at the White Paintings Shelter followed a specific procurement strategy to obtain these silcrete raw materials (Nash *et al*., 2013).

1.2.3 Characterising and Defining Archaeological Quartzite

The most abundant raw material at both OBP and Mwulu's Cave is quartzite. For this reason, I present previous studies that performed analyses on quartzite.

Prieto *et al*. (2019) studied the lithics from El Arteu and El Habario in northern Spain to determine the characteristics of quartzite based on petrogenesis. This was done through petrographic analysis (qualitative and quantitative) and XRF.

The term 'quartzite' has been used incorrectly in some archaeological studies. It is important to resolve this issue because without a unanimous definition for quartzite, there is a continued loss of information and a bias in understanding procurement strategies. Prieto *et al*. (2019) overcame this issue through the petrographic characterisation of quartzite. This is important especially when quartzite is one of the most abundant raw materials used to knap tools (Prieto *et al*., 2019). Extensive studies on obsidian and flint raw material procurement analyses have been conducted but only a few on quartzite. In the Cantabrian region (Spain) a study of quartzite has been attempted before but only on a macroscopic scale and not through petrographic means (Alonso *et al*., 2013, as mentioned by Prieto *et al.* (2019)). In 2017, Sunyer *et al*. characterised quartzite according to petrographic characteristics such as grain size, colour, inclusions, foliation, and alterations of the matrix. Prieto *et al*. (2019) used quartzite petrogenesis criteria by authors such as Hirth *et al*. (2001), Folk (1980) and Stipp *et al*. (2010) to characterise quartzite. First, they characterised quartz grains according to the following criteria:

- Detrital quartz grains;
- Grains with concave-convex grain boundaries;
- Undulose extinction in quartz grains;
- Regrowth of quartz syntaxial cement;

- Serrated boundaries or stylolites;
- Presence of Böhm lamellae;
- Presence of recrystallized grains;

The second method they used to define quartzite was the metric characterisation of size, orientation and shape through digital image processing (Manzano *et al*., 2005 as mentioned by Prieto *et al*. (2019)).

Lastly, mineralogical characterisation according to criteria described by Yardley *et al*. (1997) and Perkins and Henke (2002; mentioned by Prieto *et al.*, 2019) was conducted. After obtaining petrographic results, the quartzites were grouped by relating petrographic characteristics to petrogenesis based on geological studies (Folk, 1980; Howard, 2005). From this analysis, six quartzite types were found and characterised as sedimentary, orthoquartzite or metamorphic (Figure 1.2) (Prieto *et al*., 2019).

In my current study, quartzite will be classified based on Howard (2005) as a metamorphosed, quartz-rich rock that fractures through grains and cement, and not around them. Microscopically, it is polycrystalline and shows interlocking crystals with less than 1% intergranular porosity (Howard, 2005). In contrast to quartzite, sandstone is a sedimentary rock composed of sand-sized grains (predominantly quartz, feldspars, and rock fragmemts) surrounded by matrix in the interstitial spaces around them (Boggs, 2009). It fractues around grains and not through them. Shales are defined as siliciclastic sedimentary rocks that are very fine silt grained and are predominantly composed of clay minerals, micas, quartz, and feldspars (Boggs, 2009). Quartz, is a monocrystalline mineral that can be found in veins or as pebbles in conglomerates. Dolerite is a basaltic igneous rock composed of fine to medium sand sized grains. It is usually composed of pyroxene, feldspars, olivine, and opaque minerals (Mckenzie *et al.*, 2017). Chert is a very dense, fine-grained rock composed of silica in the form of mineral quartz (Boggs, 2009).

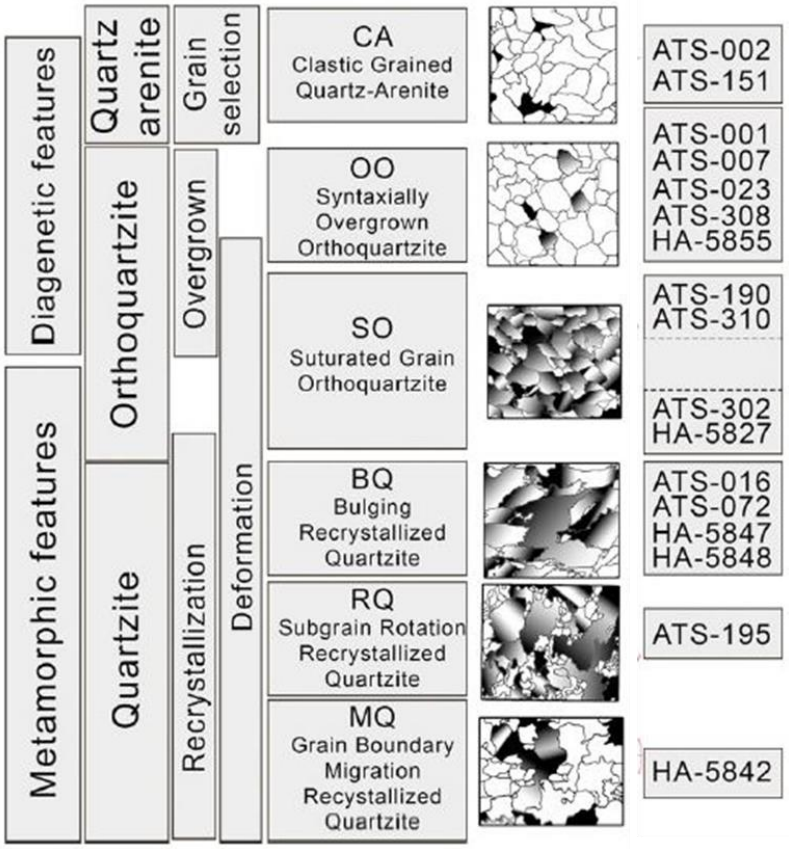

Figure 1.2: Schematic representation of defined quartz-rich rock types (modified from Prieto *et al*., 2019).

1.3 Geographic and Archaeological background of the sites

1.3.1 Olieboomspoort Rock Shelter

OBP is a long and narrow shelter at the base of an almost vertical, red sandstone cliff (Figure 1.3). This cliff is found in a valley in the jagged Waterberg Mountain Range (Figure 1.4), northern Limpopo (23˚52'42" S; 27˚38' 17" E) (Val *et al*., 2021). The slope across the area is described as dipping gently to the north, although large expanses between mountains are relatively flat. OBP is located a few metres from the perennial Rietspruit River. The site formed through weathering of the underlying bedrock and erosion of the roof and walls as a result of fluvial activity by the Rietspruit River (Val *et al*., 2021). Vegetation around the site belongs to the savanna biome. There are C_4 grasses, savanna trees, and Bushveld fauna close to OBP.

An Acheulean to Later Stone Age occupation history is documented at OBP (van der Ryst, 2007). The lithic raw materials identified in the first study at this site are quartzite, quartz, hornfels, and dolerite (van der Ryst, 2007). Felsites, mudrocks, and chalcedony have also been identified as raw materials through previous studies. Other findings at the site include rock art, faunal remains, pollen, and phytoliths (Val *et al*., 2021).

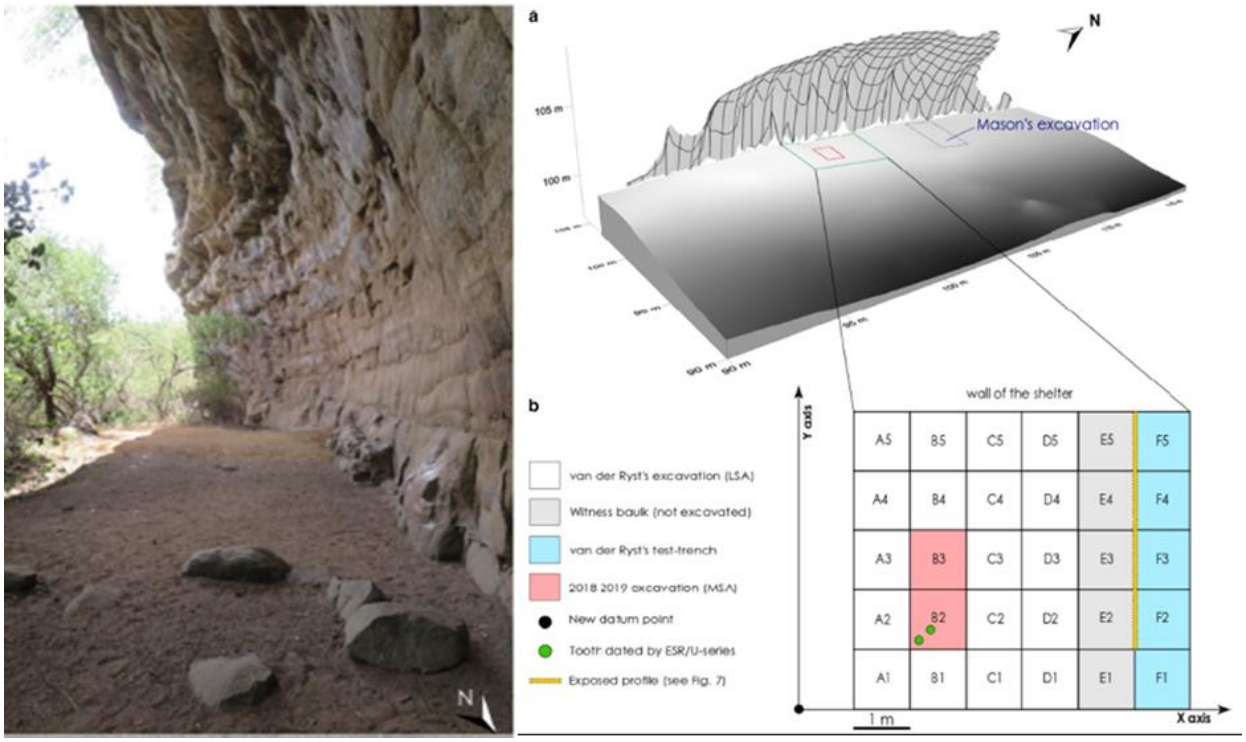

Figure 1.3: Left: North view of the site before the site was reopened by Val *et al*. (2021). Right: Image showing positions of all excavations and associated information. Figure from Val *et al*. (2021).

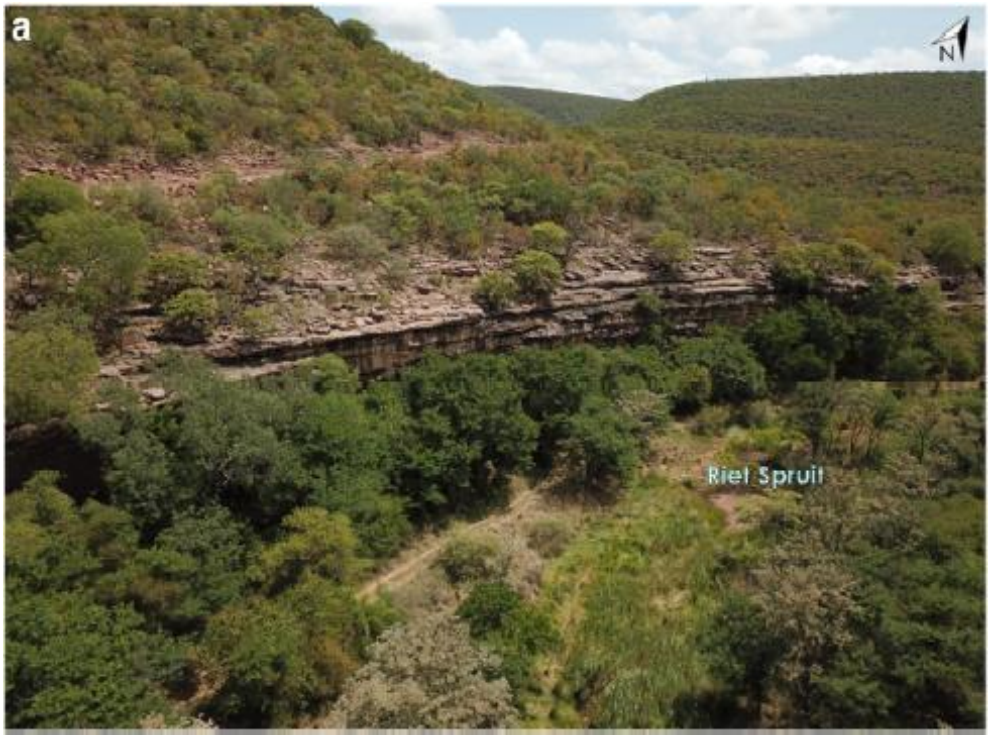

Figure 1.4: Drone image showing vegetation and of the red sandstone cliff (picture courtesy of S. Küsel). Picture from Val *et al*. (2021).

Site Formation Hypothesis

OBP has been reworked by geogenic, biochemical, biogenic and anthropogenic processes. These processes affect OBP due to its size, its open nature, its proximity to a river, and its position in the Mogalakwena Formation (Val *et al*., 2021). These processes are elaborated in order of appearance below.

The Riet Spruit tributary has eroded the quartzites of the Mogalakwena Formation along its cut bank. Gradual weathering has also eroded finer shale material at bedding contacts, depositing angular concave quartzite clasts at the site. These same processes have caused the breakdown of the shelter's roof and walls, depositing fluvial particles and cobbles. Ultimately, a calcified talus formed from this material (Val *et al*., 2021).

In terms of biochemical processes, organic preservation at the site has been affected by the excrement of animals like baboons and hyraxes. Anthropogenic chemical effects from cooking and burning material have also disturbed organic preservation (Val *et al*., 2021). Biogenic and anthropogenic processes like trampling, bioturbation and

burrowing, as well as mechanical accumulation and modification of material by hominins and animals, has affected archaeological material at the site (Val *et al*., 2021).

History of Excavations

OBP has had three main archaeological excavation campaigns since it was discovered by Mason in the 1950s. He conducted the first campaign in 1954, providing initial descriptions of lithic artefacts at the site. A 3.5 m long test trench was dug in spits because the shelter lacked a coherent stratigraphy. This method of excavation continued until what he believed to be the bedrock at 2 m depth (Mason, 1962). This campaign yielded a vast lithic assemblage of over 1495 lithics, 145 of which are cores. Preliminary analyses identify the lithic raw materials as quartzite, quartz, felsite, mudstone, chalcedony and other cryptocrystalline silicates (Val *et al*., 2021). No bone artefacts were excavated, an occurrence Mason (1962) attributes to the ubiquity of rock supply in the area.

In 1997, van der Ryst excavated at OBP to analyse the Holocene layers. Two excavations took place over more than six campaigns. The first was a 1 m x 5 m x 2 m test trench dug to define a general stratigraphy at the site. This was not fulfilled because van der Ryst (2007) could not establish a defined stratigraphy. The second 20 m² excavation (1 m from the test trench) was dug in 5 cm spits until the contact between the Middle Stone Age and the Later Stone Age (1 m deep). This was done to explore Later Stone Age occupations and to recover additional archaeological artefacts from the site (van der Ryst, 2007).

Recently, Val *et al*. (2021) excavated 30 *décapages* in two sedimentary units at OBP using the same square numbering strategy. This excavation had three main objectives. The first was to reopen van der Ryst's principal excavation. The second objective was to see if a more extensive excavation was necessary. The final objective was to exhume van der Ryst's test trench for dating, and for archaeo-botanical and geo-archaeological purposes (Val *et al*., 2021).

Archaeological deposit and stratigraphy

The archaeological sequence at OBP was initially divided into four chrono-cultural beds by Mason (1962) and van der Ryst (2007). The first (Bed 1) overlies the mentioned bedrock and the fourth (Bed 4) is the surface layer. Bed 1 is represented by Early Stone Age, possibly Acheulean, artefacts as recorded by both Mason (1962) and van der Ryst (2007). Mason (1962) exhumed bifaces that belong to the later Acheulean, while van der Ryst (2007) exhumed a sandstone handaxe and cleaver from Bed 1. Bed 2, which represents the MSA, was considered the middle of the Pietersburg Industry by Mason (1962). Bed 3 and 4 are the younger constituents at the top of the archaeological sequence. Together these two beds are only 1 m thick with Bed 3 being the thicker layer and Bed 4 representing Iron Age occupation (Val *et al*., 2021).

Val *et al*. (2021) excavated 20 *décapages* in the Grey-Sand unit (GS) and 10 *décapages* in the Yellow-Reddish Sand unit (YRS) at OBP. The GS unit is comprised of a soft grey matrix with medium to coarse clasts whereas the YRS is comprised of coarse, red, clast-supported sediment (less than 15% matrix). They provide a detailed description of the archaeological sequence. The beds have been grouped into two sedimentary units, namely the Upper unit and the Lower unit. The Upper unit (Bed 3 and 4) is separated from the Lower unit by a sharp unconformity, suggesting an erosive event or a pause in deposition (Val *et al*., 2021). The upper surface of the Upper unit has been eroded and overlies matrix-supported, sandy and silty, stratified and graded strata. The unit is slightly cross-bedded with well-sorted sediment in which a few disseminated, angular to sub-rounded clasts are noted (Val *et al*., 2021). Geogenic, anthropogenic, and chemical processes are evident through the deformation of strata; the presence of faecal matter, roots, ash, coal and rubified sediments; as well as calcite precipitation on some artefacts (Val *et al*., 2021). Unlike the Upper unit, the Lower unit contains fresh artefacts in its upper layers. It does, however, have a sandy to silty sediment nature although the clasts are poorly sorted. These clasts are of varying shapes and sizes. They are large sub-rounded cobbles and angular blocks and boulders near the talus. These become small-medium, angular to sub-rounded clasts towards the centre and eastern regions of the shelter (Val *et al*., 2021). Clasts that have undergone calcification and water saturation were noted at the talus and in the middle layers of this unit. These clasts are oriented in

a planar fabric which slopes W-E before the dripline and E-W towards the shelter wall. At the very bottom, clasts-supported layers that were affected by chemical and mechanical processes bear calcified artefacts and sediments (Val *et al*., 2021). Val *et al*. (2021) uncovered MSA artefacts below the 'bedrock' as noted by Mason (1962) and van der Ryst (2007). Based on this finding, they suggest that the true bedrock may lie a further 1m deeper than previously noted.

Dating

The Val *et al.* (2021) excavation campaigns unearthed teeth from the GS layers (*décapage* 11 and 13) for the purpose of dating through Uranium Series and Electron Spin Resonance techniques. From these methods, they found that the teeth dated around 150 ka, placing the site in Marine Isotope Stage 6 (191 ka to 130 ka) (Val *et al*., 2021).

1.3.2 Mwulu's Cave

Mwulu's Cave is located on a quartzite cliff at the top of one of the Makapansberg Mountains in Mokopane. It is situated 30 m below an overhanging quartzite ledge and 15 m above the base of a north-facing cliff in a mountain pass (de la Peña *et al.*, 2019). The cave is found after a steep, rocky, and heavily vegetated mountain pass (which is known in the area as 'Monkey Pass') above a vertical and narrow climbable path (Figure 1.5). The valley lies right below the cave and the flat plains are seen at a distance. The abundant vegetation in this region predominantly belongs to the savanna biome (Polokwane Plateau Bushveld and Mamabolo Mountain Bushveld) (Rutherford *et al.*, 2006). The savanna biome in this area is represented by small trees, shrubs and succulents on the hills and mountains, and sparse trees and C_4 grasses across the high-lying plains (Rutherford *et al.*, 2006). The raw materials represented in the lithic assemblage at Mwulu's Cave include quartzite, quartz, and chert according to preliminary analyses (de la Peña *et al*., 2019). There are, however, other raw materials that still need to be identified from the lithics collected at the site. Technologically, *Levallois* flakes, flake fragments and blades dominate in this assemblage. Documented

is also a low amount of retouched material such as side-scrapers, notches, denticulates and unifacial points. No faunal remains have been preserved (de la Peña *et al.,* 2019).

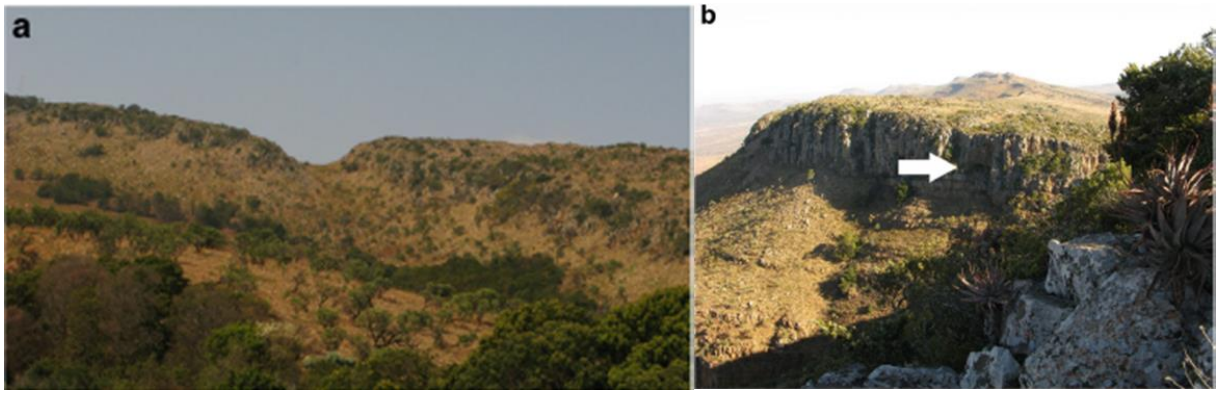

Figure 1.5: a) A picture of Monkey Pass and b) Mwulu's Cave (de la Peña *et al.,* 2019).

Site Formation Hypothesis

Mwulu's Cave is positioned 5 m below two diverging joints in the cliff (A: Figure 1.6). The cave probably formed as a result of the collapse of quartzite (de la Peña *et al*., 2019).). This collapse took place in response to the NE-SW fracturing that formed the steep fault-controlled valley and cliff complex (Maguire, 2009). The breakdown and expansion of the cave are caused by vertical joints in the walls and the roof. It is also caused by the percolation of fluids throughout the cave's expanse (de la Peña *et al*., 2019). The floor of the cave is littered with quartzite boulders (B: Figure 1.6).

Figure 1.6: Left: Photo of two diverging joints above the roof of the cave (courtesy of Dr Zubair Jinnah). Right: View of the interior of the cave. It extends 14 m into the cliff and its entrance is 8 m wide (de la Peña *et al.*, 2019).

History of Excavations

Mwulu's Cave was given its name by Maguire after an elderly hermit called Moholo who lived in the cave in the 1800s (de la Peña *et al*., 2019). The people of the area still refer to the site as 'Moholo' to this day, although the name that has passed to the scientific literature is Mwulu. Since the cave was found, it was excavated over three campaigns.

In 1947, Tobias excavated the cave but left very little information on its location and the spatial data of the findings during his excavation. However, it is known that he used Malan's excavation method (Malan; Cooke; and Wells, 1945), to establish a grid. He used spits to excavate half of the cave's deposits and defined a stratigraphy until the bedrock (de la Peña *et al*., 2019).

De la Peña *et al*. (2019) excavated the site in two different campaigns in 2017.

Archaeological Deposit and Stratigraphy

P.V Tobias excavated the site in 1947 and documented the stratigraphy in 5 layers. These include (from youngest to oldest) 1) the Ash and Sand 3 layer overlain by surface rubble, 2) the Red Sand layer, 3) the Ash and Sand 2 layer, 4) the Red Sand layer, and

finally 5) the Ash and Sand 1 layer (Tobias, 1949). According to Tobias (1949), only the Ash and Sand layers offered archaeological lithic material.

After the de la Peña and colleagues (2019) excavation campaigns, a few major findings concerning site stratigraphy were noted. Stratigraphic units at the site were established before excavations. These units were determined based on colour, content, texture, structure, and clast fabric. They lack clearly visible internal stratigraphy and are very similar to those recorded by Tobias (1954) (Figure 1.7). The only conformable contact that was noted is between stratigraphic layers 1 and 2 (de la Peña *et al*., 2019). Unconsolidated and structureless sediments with sandy to loam textures have been described at the site. Within them, aeolian and autogenic sands (produced by changes in the delta lobe that are controlled by 'internal' processes, e.g. depositional slopes) with ash, organic and faecal material, moisture, and lithics are noted. The colour of the sediments ranges from pale grey to dark brown, and red-brown (de la Peña *et al*., 2019). It is proposed by de la Peña *et al*. (2019) that instead of using sedimentology to divide units, divisions should be based on the archaeologically excavated layers. This produces three main archaeological units based on their lithic spatial statistical analyses. They are the Uppermost Unit 1 (Tobias' Ash and Sand Layer 3), the Middle Unit 2 (Tobias' Red Sand Layer), and the Lower Unit 3, 4 and 5 (Tobias' Ash and Sand Layer 2 and 3 and the Red Sand Layer between them) (de la Peña *et al*., 2019).

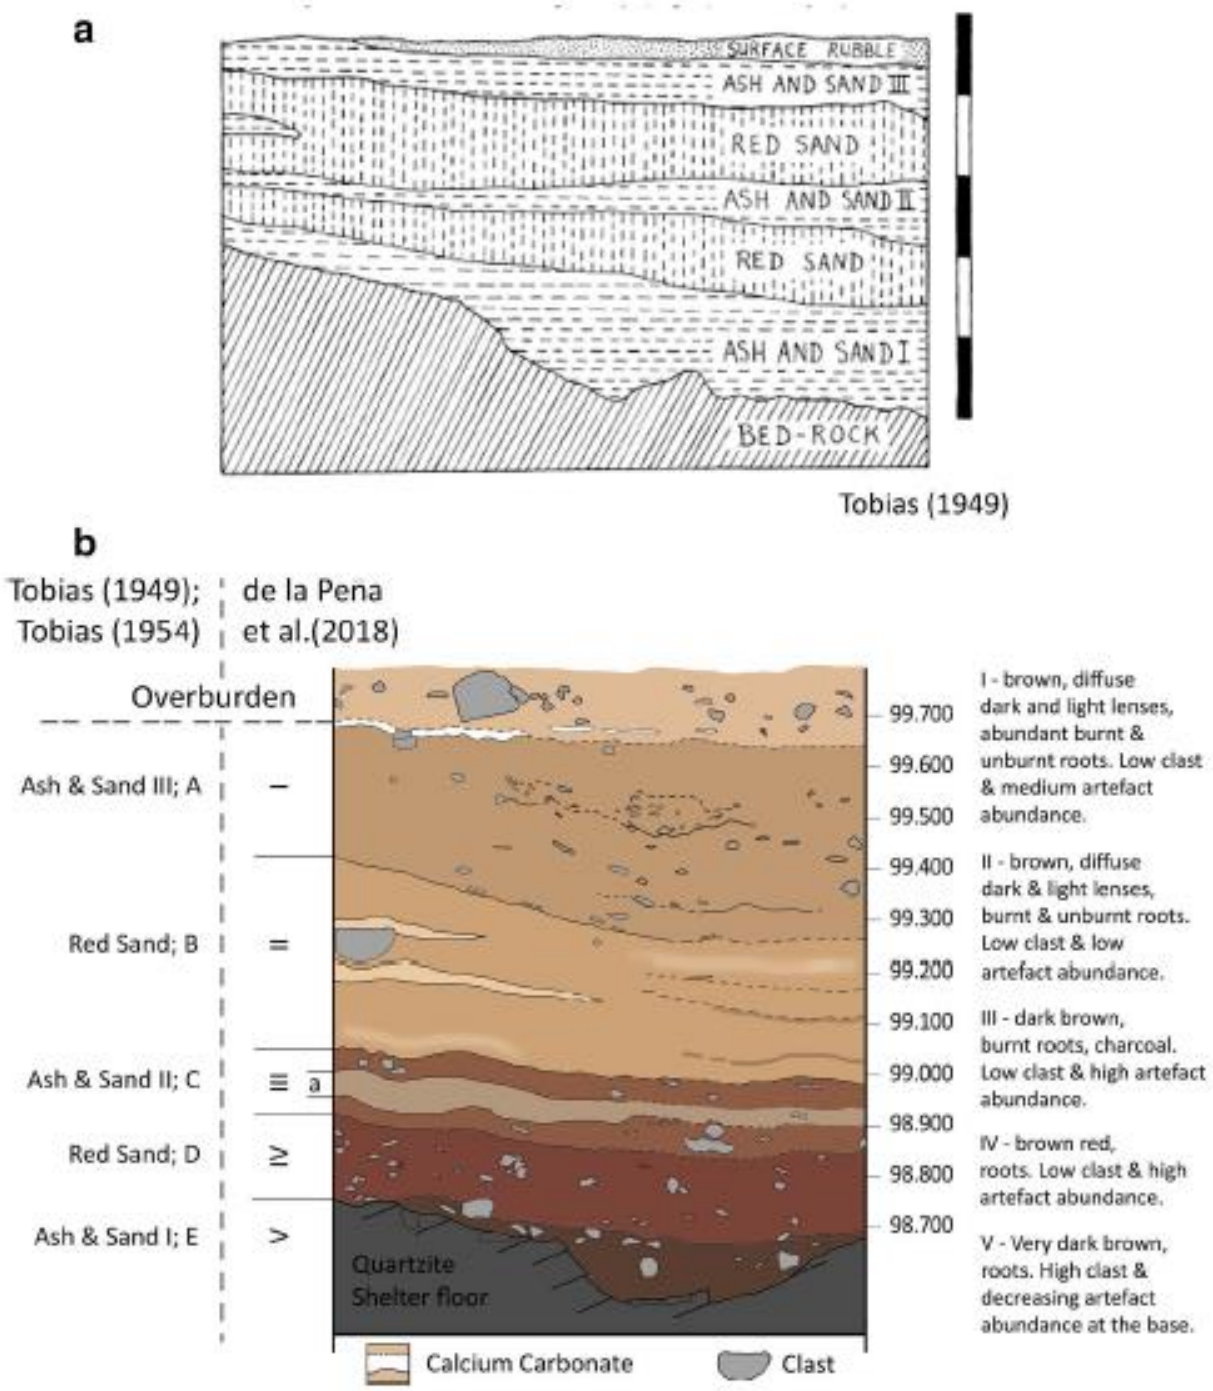

Figure 1.7: Image shows a) Tobias' stratigraphic sequence and b) the de la Peña *et al.* (2019) stratigraphic sequence with depths on the right vertical axis (total station-derived). The left vertical axis shows Tobias' stratigraphic divisions and nomenclature (1949, 1954) and the units identified in the field in 2017 (I–V) (de la Peña *et al.*, 2019).

Dating

Mwulu's Cave was attributed to the Pietersburg Industry by Tobias (1949) and dates back to around 90 ka based on luminescence dating of feldspar lithics (Feathers *et al*., 2020).

1.4 Aims and Objectives

This project focuses on the raw material provenance and procurement analysis of lithic assemblages at OBP and Mwulu's Cave. The aim is to find the provenance of the lithics and to determine the procurement strategies of hominins at OBP and Mwulu's Cave.

The objectives of the project are to identify the rocks used to make stone tools at the sites through petrographic and geochemical analyses. This information is linked to the regional geology of the area. Petrography (stereomicroscopic analysis and thin sections) is used to investigate visual qualities that distinguish the rock types. Elemental analyses (X-ray fluorescence and Induced Coupled Plasma Mass Spectrometry) are used to group materials according to chemical signatures. Geological maps are consulted for locating outcrops and gauging the regional geology around the sites.

Relating the lithics to the regional geology will suggest potential outcrops that were exploited in the MSA.

1.5 Hypothesis

Hominins at OBP and Mwulu's Cave had a local procurement strategy when collecting raw materials for lithic production. They often sourced readily available raw materials close to their sites, similar to hominins at other MSA sites.

2 GEOLOGY OF STUDY AREAS

2.1 Olieboomspoort Rock Shelter Associated Geology

Olieboomspoort Rock Shelter lies at the base of a vertical cliff made of red sandstone between two mountains in the Waterberg Mountain Range. The mountains look jagged due to the persistence of conglomerate/ pebble lag strata that are not easily weathered. The slope across this area dips gently to the north and large expanses between mountains are relatively flat. OBP is located virtually on the bend of the perennial Riet Spruit river channel and is surrounded by abundant vegetation (Figure 1.4).

The shelter is located in the Mogalakwena Formation of the Waterberg Group (Figure 2.1). The stratigraphy and lithology, as well as important geochemical information, associated with the region, are described below.

2.1.1 The Waterberg Group

The Waterberg Group is located in the Waterberg Main Basin (Figure 2.2) in the NNW of South Africa. This basin is fault-controlled and bounded by the Melinda (Palala) fault zone in the north and the Thabazimbi-Murchison Lineament in the south (Eriksson *et al*., 2008). The Waterberg Group is a clastic sedimentary succession that was deposited between 1.95 and 1.7 Ga in the Waterberg Main Basin, in the Kaapvaal Craton (Eriksson *et al.*, 2000; Barker *et al*., 2006). Rocks of the Waterberg Group received sediment from the erosion of the Limpopo Belt (Corcoran *et al*., 2013).

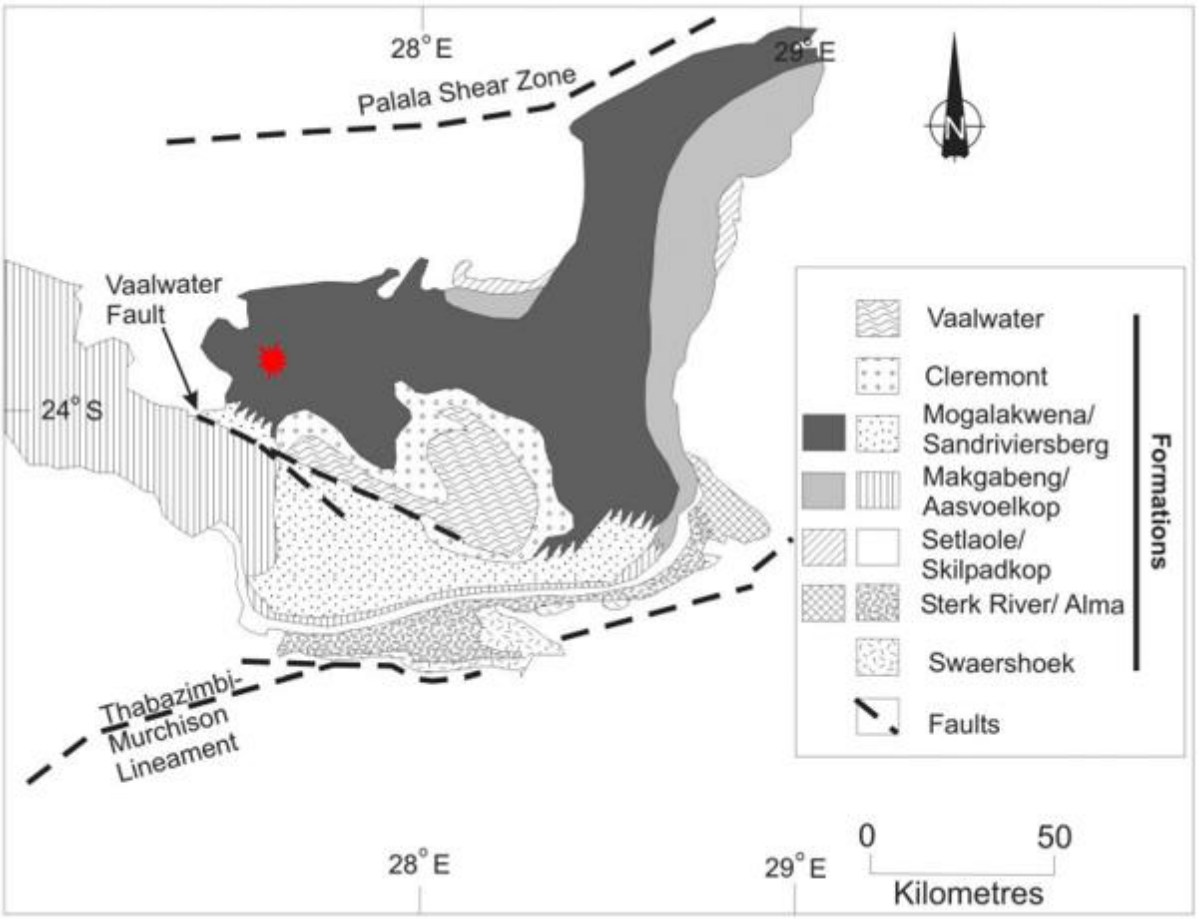

Figure 2.1: Geological sketch map of the Waterberg Group in the Waterberg Main Basin showing the Melinda (Palala) fault zone, the Vaalwater fault, and the Thabazimbi-Murchison Lineament. Formations of the Waterberg Group are represented according to the legend. Olieboomspoort Rock Shelter is represented by the red star. (Eriksson *et al.*, 2008).

It consists of eleven formations (Figure 2.2; Eriksson *et al*., 2008). In this project, formations in the NNE to the centre of the Waterberg Main Basin are briefly discussed and only the Mogalakwena Formation is discussed in detail. These, from oldest to youngest, are the Blouberg Formation, the Setlaole Formation, the Makgabeng Formation, the Mogalakwena Formation, and the youngest Cleremont and Vaalwater Formations (Eriksson *et al*., 2008).

1. The Blouberg Formation is made of 1400 m of mineralogically and texturally immature sandstones and conglomerates (Eriksson *et al*., 2008).

2. The 450 m thick Setlaole Formation is located in the NE of the Waterberg Main Basin and has a lithostratigraphy consisting of arkose- and granule-rich sandstones and conglomerates. Basal tuffs are also noted (Eriksson *et al*., 2008).
3. In the NE of the basin, the 800 m thick Makgabeng Formation conformably overlies the Setlaole Formation. It is characterised by palaeodesert deposits (palaeodune sediments with wadi-fluvial, interdune, and saline pan sediments) (Eriksson *et al*., 2008).
4. The Mogalakwena Formation, which will be discussed in further detail, is a 1250 m thick unit on the NE side of the Vaalwater fault. It consists of sandstones and conglomerates (Eriksson *et al*., 2008).
5. The youngest Cleremont and Vaalwater Formations are found in the centre of the Waterberg Main Basin and have mature sandstones (Eriksson *et al.*, 2008).

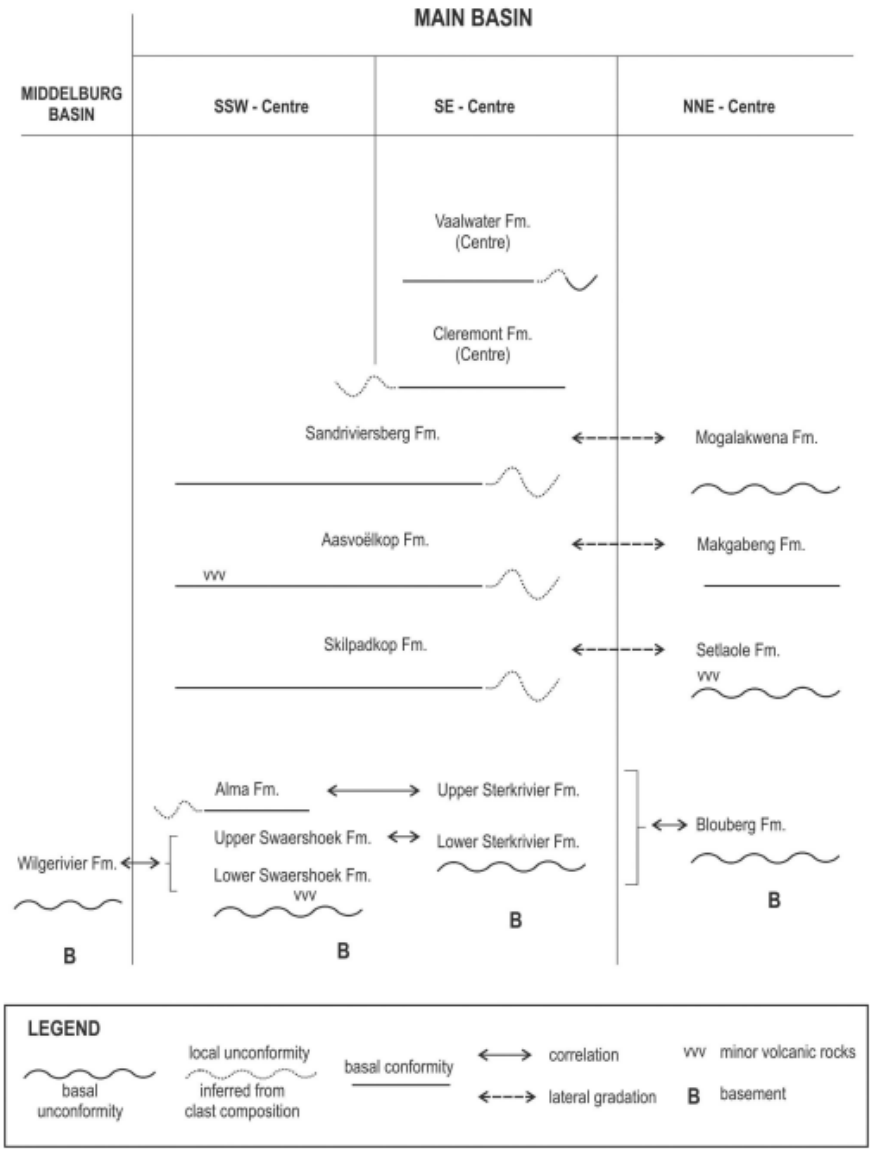

Figure 2.2 The stratigraphic subdivision of the Waterberg Group shows the formations in different areas of the Main Basin. The inferred correlations and contacts are also shown (modified after Eriksson *et al.* (2006)).

2.1.2 The Mogalakwena Formation

The Mogalakwena Formation is comprised of well-sorted red/purple-brown granular/coarse-grained sandstones and quartz-conglomerates (1.9 to 1.7 billion years old (Eriksson *et al.*, 2000)) that dip gently to the north and are interbedded with

micaceous shales (Tickell, 1975; Brandl, 1996). It is unconformably deposited on the Makgabeng Formation and the steeply dipping Blouberg Formation in the north (Corcoran *et al*., 2013). It has also been noted that dolerite dykes (1.92-1.87 Ga: Corcoran *et al*., 2013), that are located south of the Eenzaamheid Fault, are present in the Mogalakwena Formation although they may be difficult to see due to extensive weathering (Fourie *et al*., 2014). The brown sandstones are quartz-rich (Figure 2.3). Tickell (1975) notes quartz wackes and lithic wackes; Callaghan (1987) notes litharenites and sublitharenites; Bumby (2007) notes sandstones with less than 50% quartz in them. They are composed of medium to granule, sub-angular to sub-rounded grains in fine sericite and coarse muscovite matrix (Tickell, 1975; Corcoran et al., 2013). Carbonate and silica cement is also common. The grains in the sandstones are upward fining and a low-angle lamination is noted (Corcoran *et al*., 2013). The conglomerate lithofacies show a variation from massive to planar and trough crossbedding and include well-rounded quartz and quartzite pebbles (3-10 cm) (Tickell, 1975; Eriksson *et al*., 2008; Corcoran *et al*., 2013). Arenite and chert account for over 90% of lithic fragments although minor siliceous gneiss fragments are also noted (Corcoran *et al*., 2013). Eriksson *et al*. (2008) summarise the sandstones as significantly variable with textural and mineralogical immaturity. The lithostratigraphy of the Waterberg Group is shown in Table 2.1.

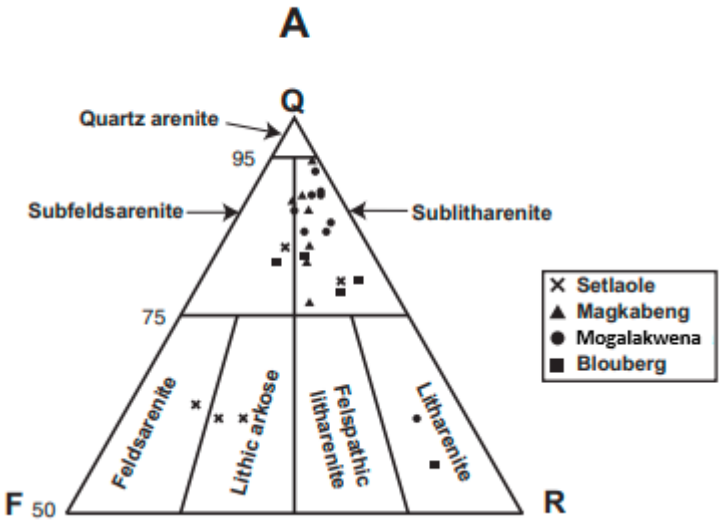

Figure 2.3: Ternary diagrams showing the compositions of samples from the Waterberg Group formations as analysed and plotted by Corcoran *et al*. (2013). (A) QFR diagram of Folk *et al*. (1970), truncated at 50% quartz.

Table 2.1: Lithostratigraphy of the Waterberg Group (Callaghan *et al*., 1991).

GROUP	SUBGROUP	South / southwest & central parts	Southeast & central parts	North / northeast & central parts	Nylstroom area	Middelburg area
WATERBERG GROUP	KRANSBERG	Vaalwater Formation (475m)				
		Cleremont Formation (125m)				
		Sandriviersberg Formation (1250m)	Sandriviersberg/ Mogalakwena Formations	Mogalakwena Formation (1250-1500m)	Sheets of coarse sandstone and granulestone, interbedded with sheets of conglomerate. Fluvial origin	
	MATLABAS	Aasvoelkop Formation (300-600m)	Aasvoelkop/ Makgabeng Formations	Makgabeng Formation (380-1000m)	Large-scale trough and planar cross-beds of fine-/medium-grained sandstone. Aeolian origin	
		Skilpadkop Formation (450-600m)	Skilpadkop Formation (450-600m)	Setlaole Formation (450m)	Coarse sandstone and granule-stone with rare conglomerate. Fluvial origin	
	NYLSTROOM	Alma Formation (3000m)	Sterk River Formation (500-1500m)		Alma Formation	
		Swaershoek Formation			Swaershoek Formation (2500m)	Wilge River Formation

In terms of palaeoenvironments, a fluvial depositional environment is suggested for the Mogalakwena Formation. This suggestion stems from the local conglomerate-filled channels and coarse-grained sandstone sheets (trough cross-bedded) which indicate the migration of low sinuosity braided fluvial channels (Tickell, 1975; Corcoran *et al*., 2013). The sub-rounded nature of some quartz grains in the unit indicates transport of the grains, albeit relatively short. The palaeocurrent patterns described suggest that the rivers flowed from NE to SW (Tickell, 1975; Corcoran *et al*., 2013).

Corcoran *et al*. (2013) analysed the geochemistry of the Mogalakwena Formation green and brown sandstones, as well as its shales. It is mentioned that this formation is unique in that it shows elevated Ti and Zn values and intra-formational differences in Rare Earth Element (REE) patterns (Corcoran *et al*., 2013). The sandstones in the formation are shown, through the study of Corcoran *et al*. (2013), to have undergone a degree of recycling as this could explain the Al_2O_3 enrichment relative to Na_2O_3, CaO and K_2O noted in their results. This observation is supported by the fact that combinations of well-rounded and sub-angular quartz grains are evident in the lithology (Corcoran *et al.*, 2013). Brown sandstones in the formation are reported at 81-89 wt% SiO_2 and the green sandstones have reported abundances of Cr, Ni, V, Ti and Zn as well as a lower Th/Sc ratio than any other sandstone in the Waterberg Group. The sandstones and shales analysed by Corcoran *et al*. (2013) have shown average Ti and Zr compositions of 4098 ppm and 294 ppm respectively, which are the highest values in their sample suite. It is also mentioned that these sandstones and shales have been Light Rare Earth Elements (LREE) enriched with La/Yb values that range from 6.03 to 24.20 ppm (large variation consistent with mixed provenance) (Corcoran *et al*., 2013).

2.2 Mwulu's Cave Associated Geology

Mwulu's Cave is located on a quartzite cliff in a valley within the Makapansberg Mountains (de la Peña *et al*., 2019). The area around the cave is full of boulders and cobbles and vegetation cover is abundant. A valley lies right below the cave and flat plains are seen at a distance.

The cave is situated within the Black Reef Quartzite Formation (BRQF) which is found in the Transvaal Basin of the Transvaal Supergroup. This unit was deposited during the Archaean (Van den Berg, 1994) in a fluvial to shallow marine environment as noted through characteristics in its siliciclastic sediments (mature quartz arenites, lesser conglomerates and dispersed mudrocks) (Mcloughlin, 2015). More on stratigraphy, lithology, and geochemistry associated with the study is discussed below.

2.2.1 The Transvaal Supergroup

The Transvaal Supergroup sedimentary succession is present in three structural basins on the Kaapvaal Craton. These are the Transvaal Basin, in which the BRQF is found, the Griqualand West Basin, and finally the Kanye Basin in Botswana (Figure 2.4). The BRQF is the oldest formation in the Transvaal Supergroup and is located above the basement rocks of the Transvaal Supergroup (Johnson *et al*., 2009). This succession has a well-preserved carbonate platform (with stromatolites) (McLoughlin, 2015). Below is a description of the stratigraphy of the Transvaal Supergroup (Figure 2.5). This is necessary to note because of the possibility of encountering alternative rock material from the archaeological lithic sample set other than from the BRQF itself.

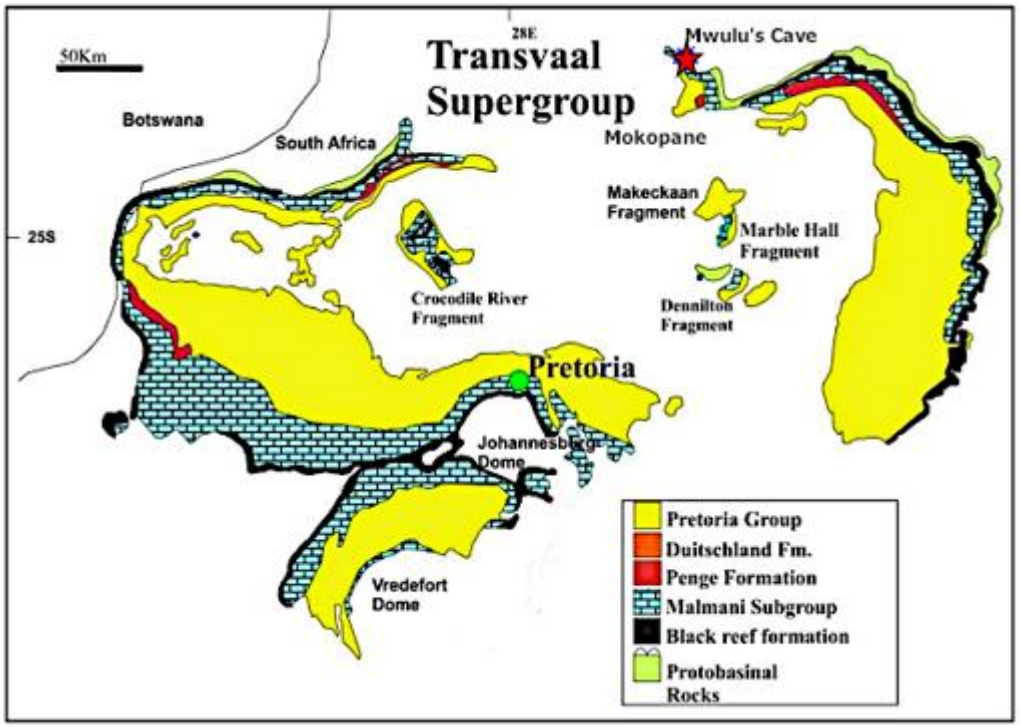

Figure 2.4: A simplified geological map of the Transvaal Supergroup stratigraphy (modified from Mcloughlin (2015)). Mwulu's Cave is on this map. Mwulu's Cave is represented by the red star.

The BQRF overlies the Transvaal Supergroup basement rocks (Wolkberg Group). Above the BRQF, Malmani Subgroup dolomites and limestones are noted (Bose *et al*., 2012). These are overlain by Penge Iron Formation marine sediments (alternating iron-rich and iron poor layers of sediment) and Duitchsland Formation lacustrine sediments (eg. shales). These last two mentioned formations make up the Chuniespoort Group that is underlain by the BRQF and followed by the Pretoria Group (Bose *et al*., 2012).

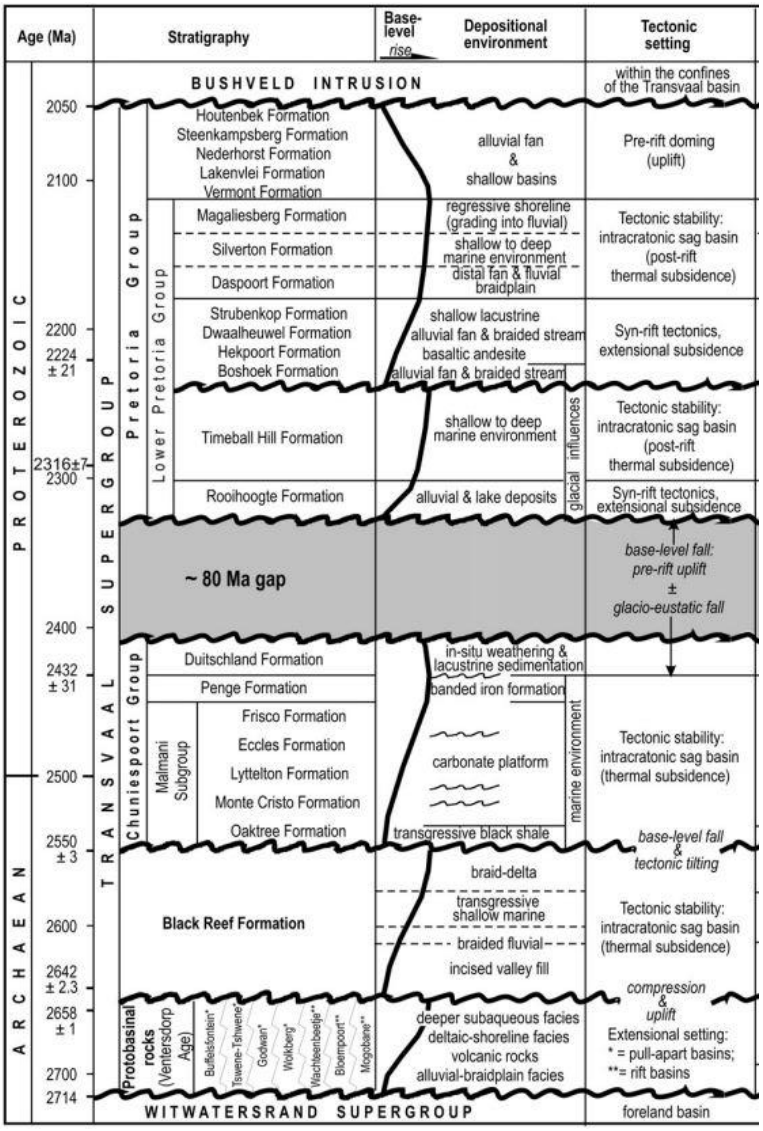

Figure 2.5: Schematic figure of the stratigraphy, depositional palaeoenvironments, tectonic settings for the Transvaal Supergroup (specifically the Transvaal basin) (McLoughlin, 2015; modified after Bose *et al.*, 2012).

2.2.2 The Black Reef Quartzite Formation (BRQF)

Mwulu's Cave is a site included within the beds of the 65 m thick Black Reef Quartzite Formation (Late Archaean to Early Proterozoic quartzites) (Transvaal Supergroup lithostratigraphy shown in Table 2.2) (Eriksson *et al.*, 1995). The BRQF may only be 65 m thick but Crocodile River Dome, Denniton Dome and Marble Hall inliers reach thicknesses of 280 m, 210 m, and 170 m, respectively. This means that the BRQF

thickens towards the centre of the Transvaal basin (Hartzer, 1994). The BRQF lies unconformably (angular) at the base of the Transvaal Supergroup and was deposited 2200- 2700 Ma (Van den Berg, 1994) or between 2460 and 2050 Ma (SACS, 1980). No major faulting or folding has been documented for the formation although it does rest on the pre-Transvaal palaeosurface (Els *et al*., 1995). Due to the limited amount of metamorphism and deformation, it falls within the sub-greenschist facies (Frimmel, 2014). The BRQF is an upward-fining succession with conglomerates at its base grading into quartzites which then grade into mudrocks at the top (Johnson *et al*., 2009). It dips gently to the north and south along the Rand Anticline and shares a gradational contact with the overlying dolomites of the Malmani Subgroup. BRQF outcrops are narrow and geographically limited because it is only 65 m thick (Els *et al*., 1995; Coetzee, 1996).

The general lithology of the BRQF is represented by mature quartzites with erratically-developed conglomerates and basal grits, and shales (Coetzee, 1996). BRQF quartzites are described as having a light grey, glassy lustre and a red-brown weathered surface with trough and planar crossbedding and plane beds (Coetzee, 1996). Oscillation ripple marks are visible across the quartzites and they are interbedded with finely laminated shales. The red-brown conglomerates have poorly sorted but well-cemented quartzite pebbles (well-rounded) of ≤15 mm diameter. Other pebble lithologies are present depending on the underlying palaeosurface (Coetzee, 1996).

According to Coetzee (1996), the depositional environment of the BRQF is of a fluvial nature (braided river channels) in the lower succession and a tidal nature in the upper part of the succession. This suggests that a marine transgression may have taken place (Coetzee, 1996). A more detailed account of the depositional environment is discussed in McLoughlin's dissertation (2015). He mentions that in its initial stages the depositional environment was a river system characterised by anastomosing braided river channels that transported sedimentary material from the Witwatersrand succession in a southward direction (De Bever, 1997). Marine transgression took place as the Transvaal basin enlarged and this caused the submergence of these channel systems. Through the active reworking of the river sediments, primary sedimentary features were lost. Basal conglomerates and quartzites at the bottom of the BRQF are fluvial and the blanket layers at the top of the sequence occur as foreshore and offshore facies (De

Bever, 1997). Therefore, as mentioned by both Coetzee (1996) and McLoughlin (2015), the overall depositional environment is siliciclastic fluvial (predominantly) and shallow marine in nature. The deposition occurred on a deeply incised erosional surface within which boulder beds, quartzites and conglomerates occur in channel facies and blanket conglomerate facies occur on the levees (Frimmel, 2014; McLoughlin, 2015).

Gold- (in-situ hydrothermal origin based on the irregular grain shape of the gold particles and the lack of evidence showing the introduction of external hydrothermal fluids into the BRQF; Frimmel, 2014) and uranium-bearing pyrite-rich oligomictic conglomerates (similar to those from the Witwatersrand) occur in both the channel and levee facies (McLoughlin, 2015). The uranium mentioned is found in the detrital uraninite and in some of the brannerite found in the Buckshot pyrite leader reef samples, which means that it was affected during the lithification of the sediments (McLoughlin, 2015).

Table 2.2: Lithostratigraphy of the Transvaal Supergroup (Coetzee, 1996).

	Groups	Formations	Dominant Lithology
Transvaal Basin	**Pretoria Group**	Magaliesberg Formation	Quartzite
		Silverton Formation	Shale and Limestone
		Daspoort Formation	Quartzite
		Strubenkop Formation	Shale and Quartzite
		Hekpoort Formation	Andesitic Lava
		Timeball Hill Formation	Shale and Quartzite
		Rooihoogte Formation	Shale, Quartzite, and Breccia
	Chuniespoort Group	Duitschland Formation	Lacustrine Sediments (Shale)
		Penge Iron Formation	Banded Iron Formation
		Malmani Subgroup	Dolomite

		Black Reef Quartzite Formation	Quartzite

3 MATERIALS AND METHODOLOGY

3.1 Materials

3.1.1 Archaeological materials

A selection of 65 lithics from OBP and 81 lithics from Mwulu's Cave was analysed. These lithics were selected from the A. Val (2018-2019) collection, and the P. de la Peña (2017) and P. Tobias (1947) collections, respectively. In the selected OBP material, quartzite makes up 43.1% of the lithic assemblage and is followed by shale (30.8%), dolerite (12.3%), sandstone (9.2%), quartz (3.1%), and chert raw materials (1.5%). The Mwulu's Cave lithic selection consists of quartzite (64.2%), shale (12.3%), quartz (13.6%), altered material (6.2%), and chert (3.7%). These lithics are flakes and fragments that were selected because they are not technologically and typologically important and they cover a variety of different rock types. Therefore, they can be analysed with destructive techniques. Table 3.1 sums up the number of lithics that were analysed from each layer at both sites.

Within the OBP collection, lithics from GS *décapages* 1, 4, 10, 13, 14, and 16, as well as those from YRS *décapages* 1, 7, and 15, were analysed.

In the Mwulu's Cave collection 23 of the 81 selected lithics are from Tobias' Bed 1-3, and 58 of the 81 selected lithics are from Layers 1-5 of the de la Peña collection of 2017.

Lithics from both sites were accessed at the Leswika Archaeology Laboratory at the Evolutionary Studies Institute (University of the Witwatersrand). Images of representative samples of the lithics (based on rock types) from both sites are shown in Figures 3.1 and 3.2. Descriptions and pictures of all the lithics can be found in APPENDIX A. Permits (ID: 3281; 3299) from the South African Heritage Resources Agency were received for the destructive analyses that were conducted on a few carefully selected lithics (unretouched flakes).

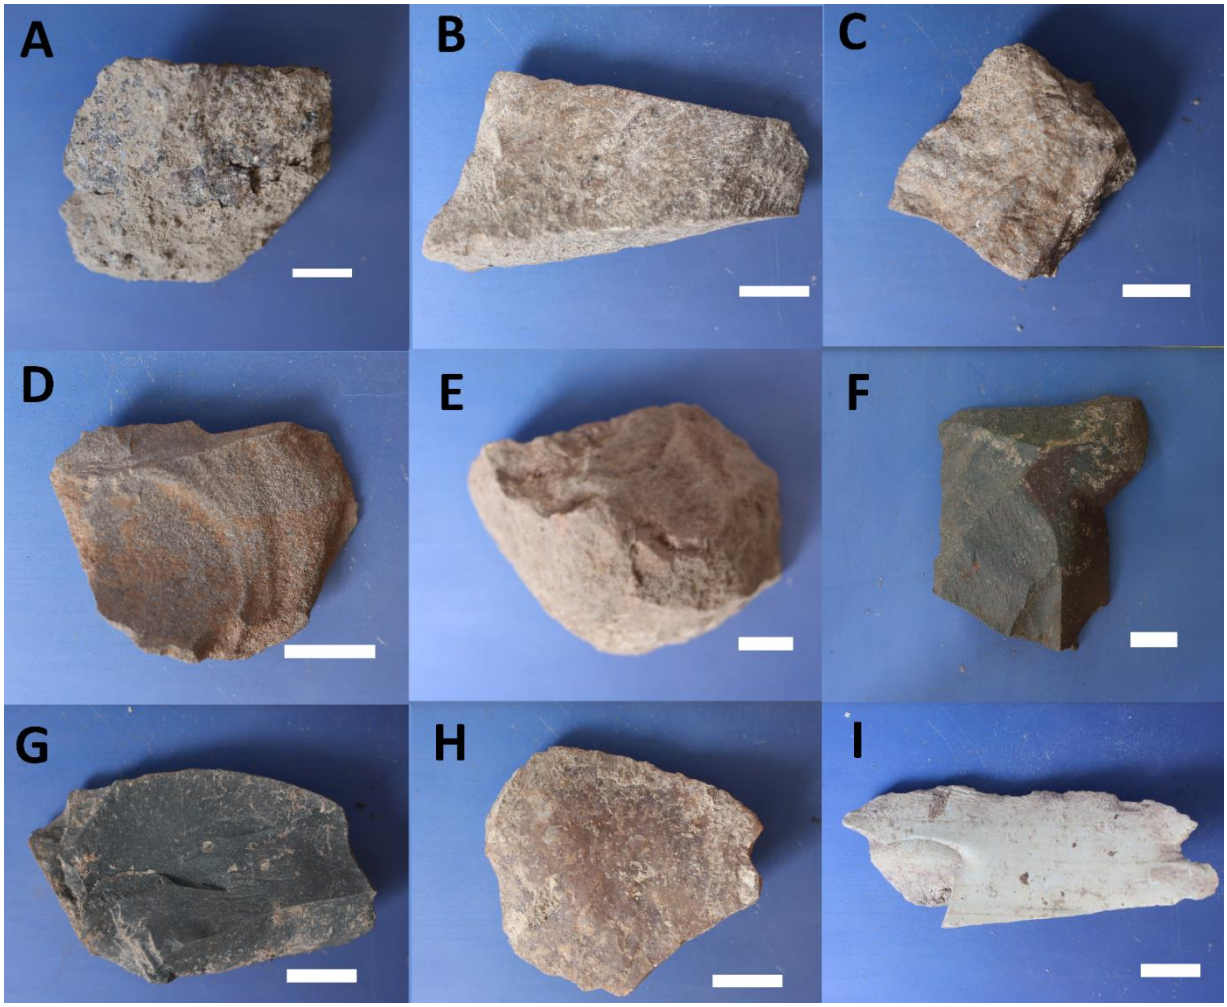

Figure 3.1: Representative samples of OBP lithics. A) No. 2402 (sandstone), B) No. 1194 (sandstone), C) No. 486 (quartzite), D) No. 458 (dolerite), E) No. 3478 (quartzite), F) YRS 1-D (shale), G) No. 164 (shale), H) No. 493 (quartz), and I) No. 412 (chert). These are all unretouched flakes. The white bar represents 1 cm.

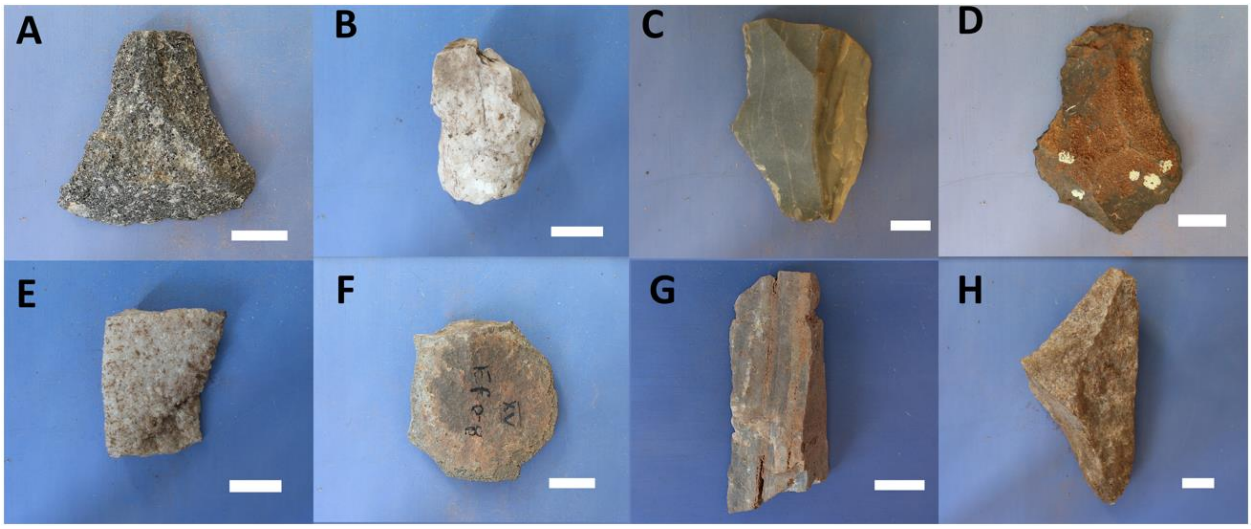

Figure 3.2: Representative sample of Mwulu's Cave lithics. A) M1-J (quartzite), B) PA-8 (quartz), C) M1-K (chert), D) M3-E (shale), E) No. 1021 (quartzite), F) M3-B (shale), G) No. 674 (banded chert), H) No. 640 (quartzite). These are all unretouched flakes. The white bar represents 1 cm.

3.1.2 Geological materials

The areas chosen for prospection surveys around OBP and Mwulu's Cave are based on the rock types of the representative samples that were selected for this study from the A. Val (2018-2019), the P. de la Peña (2017), and the P. Tobias (1947) lithic collections. This was done to link lithics to possible outcrops. Promising locations were identified using geological literature, the 2326 Ellisras Basin and 2428 Nylstroom maps (Geological Survey (South Africa)), and satellite images of the areas around the sites (Google Earth). Based on the rock types noted in the lithic assemblage and geological research, prospection areas of a 12 km radius around both sites were expected to be sufficient for geological sampling although this was not the case around OBP because of flat areas without outcrops and a lack of access to some private properties. Geological samples were taken from both primary and secondary contexts at OBP and mostly from primary contexts around Mwulu's Cave. The primary contexts are *in situ* outcrops. The secondary contexts are samples like pebbles collected along the road or river, and *ex situ* samples with the same lithology as outcrops surrounding the sites

At OBP, preliminary assessments show that the selected lithic assemblage consists of quartzite, shale, sandstone, dolerite, and quartz. These rock types (except quartzite) are expected in the Mogalakwena Formation based on geological literature (Corcoran *et al*., 2013; Geological Survey (South Africa)). Geological samples representing these rock types were collected within 30 km SSE of the site and within about 13 km NNW of OBP in the Mogalakwena Formation and the Cleremont Formation. The geological assemblage consists of 15 quartzite samples, two shale samples, five sandstone samples, four dolerite samples, and 22 quartz samples. Most of the geological samples were collected in secondary context (89.7%; *ex situ*) as pebbles and cobbles along the Rietspruit River, roads, and on a mountain at the Zandrivier Farm (Figure 3.3) although some were sampled from primary context (10.3%; *in situ*) outcrops. This was due to the lack of *in situ* outcrops in the area around OBP. Samples from *in situ* outcrops were

photographed and then removed with a geological hammer. These were then labelled and their geographical coordinates were recorded using the Garmin eTrex® GPS.

From the preliminary assessment of the Mwulu's Cave lithic assemblage, quartzite, shale, quartz, and chert rock types are noted. Based on Eriksson *et al.*, 1995, Eriksson *et al.*, 2008, and the 2428 Nylstroom map, these rock types are found in the BRQF (quartzite, quartz, shale), the Malmani Subgroup (shale and chert), and in the Duitschland Formation (shale and chert). The collection of outcrop samples around Mwulu's Cave occurred within a 12 km distance from the site within these formations. It consists of 13 quartzite samples, 16 shale samples, five quartz samples, and four chert samples, 7.9% of which are secondary context samples. Many *in situ* samples were collected around the site. The samples were collected along the road (Outcrop 1 to 10) and up the mountain towards Mwulu's Cave (Outcrop 11 to G4). Outcrop 20 and 21 samples were collected on a mountain close to the site (Figure 3.4). Similar to OBP, samples from *in situ* outcrops were photographed, removed with a geological hammer, labelled, and their GPS coordinates were recorded using the Garmin eTrex®.

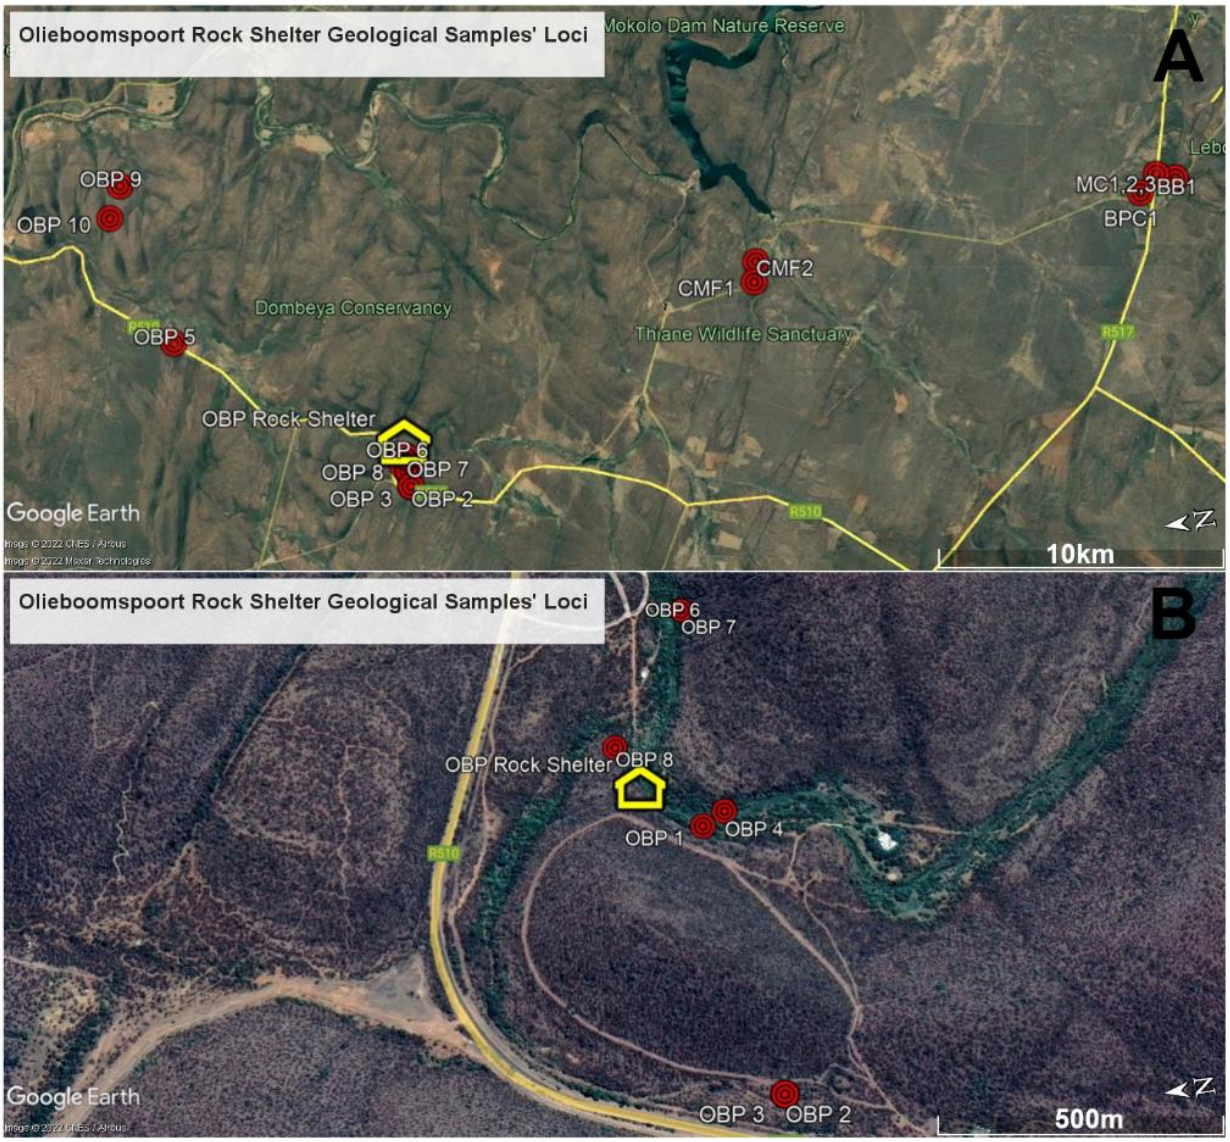

Figure 3.3: Map showing the locations from which OBP geological samples were collected, as well as the site itself (yellow house). Map A) shows all of the locations of the geological samples around OBP and B) shows locations of the geological samples that are closer to OBP. OBP is represented by the yellow house and the geological sample localities are represented by the red circles.

Figure 3.4: Maps showing the locations around Mwulu's Cave where the geological samples were collected. Map A) shows all the locations of the geological samples, B) shows Outcrop 10 at the bottom corner and G4 before the cluster around Mwulu's Cave, and C) shows the locations of outcrops immediately around Mwulu's Cave. Mwulu's Cave is represented by the red house and the outcrop/geological sample localities are represented by the yellow circles.

Each potential source is described as a 'locality' in Table 3.2. A collection of 48 geological samples from 17 localities was collected around OBP (Table 3.2). Around Mwulu's Cave, 38 geological samples from 25 localities were collected. During the prospection, general descriptions (APPENDIX A) of the outcrops were recorded and images were taken for reference.

Table 3.2: The number of samples collected at each stop, their rock types and the distance at which they were collected.

3.2 Methods

3.2.1 Macroscopic (including stereomicroscopic) analysis

Stereomicroscopic analysis of the samples was conducted with the use of an Olympus SZX16 stereomicroscope (magnification range: 0.7x -11.5x) at the Leswika Archaeology Laboratory (Evolutionary Studies Institute, University of the Witwatersrand). Petrological features that aid in rock identification and could help form general rock groups were studied. These include:

- The colour of the rock
- Lustre
- Inclusions and foliations
- Grain size
- Grain shape

- Intergranular relationships (interlocking, disseminated, etc.)
- Nature of the cortex was analysed to establish the contexts of the samples (primary or secondary)

3.2.2 Portable X-ray Fluorescence Spectrometry

Portable X-ray Fluorescence Spectrometry (pXRF) spectrometry is an analysis that quantifies the concentration of elements in a sample. It is used in this project to identify and group samples according to rock types. From these results, preliminary information about lithics and their geological sources is provided.

This method does not require much sample preparation and it produces elemental compositions relatively fast. Not only that, but it is also inexpensive and very easy to use. A few drawbacks of pXRF spectrometry are that it is unable to register light elements like Na and has low sensitivity. These drawbacks could lead to the misidentification of a rock. However, pXRF spectrometry remains a good non-destructive method (Shackley, 2011). Especially in a study such as this one because archaeological samples are being analysed and it is a priority not to destroy them. For that reason, pXRF is used to see if it can link lithics to geological samples.

Samples were analysed with no preparation using the Olympus Vanta™ pXRF instrument (40 kV beam) at the Leswika Archaeology Laboratory. The instrument is industrial and was commercially calibrated (factory calibration). The instrument was considered reliable because it provided results that were supported by ICP-MS analysis. I am, however, aware that this is not an absolute measure of accuracy. PXRF errors were provided for each analysed element although I am not certain how they were calculated since this an industrial instrument. I have included them in Appendix B (Table B3 and Table B4). Smaller lithics that could fit in the instrument were analysed while it was fixed on a stand. The larger lithics and outcrop samples that could not fit into the instrument underwent hand-held analyses. Each sample was analysed three times (45 second reading for each analysis: 15 seconds for the minor elements and 30 seconds for major elements). The beam from the pXRF instrument travelled through the air before penetrating the rock because the analyses were not conducted in a vacuum/

controlled environment. The following elements with concentrations generally above the level of detection were recorded: Al, Si, P, S, K, Ca, Ti, V, Cr, Mn, Fe, Ni, Cu, Zn, As, Rb, Sr, Y, Zr, Nb, Mo, Pb, and Th.

Principal Component Analysis

Principal Component Analysis is an unsupervised, multivariate statistical analysis. It reduces the number of variables in a dataset and maximiases variability within that dataset (Mauran *et al*., 2022).

PCA was conducted on the raw data obtained through pXRF analysis. Columns from the raw pXRF data in which more than 10% of the samples showed elemental amounts below the level of detection (LoD) were deleted. The LOD readings in the remaining columns were replaced with a constant number that is half of the minimum reading for the element. From there, PCA code (Mauran *et al*., 2022; Baxter, 1994)), and the packages ggplot2, ade4, MASS, MVN, and plyr, were used in R Studio to produce the plots to differentiate formations and to link lithics to these formations.

3.2.3 Thin section petrography

Thin section analysis provides the mineral compositions and estimates of mineral proportions in a sample. It offers the most accurate petrographic information in primary analyses (Andrefsky, 1998). This is important because mineral modal abundance estimates are pivotal in rock analysis and identification (Chaves, 1949).

The petrography of the lithics and geological samples was analysed by looking at features such as:

- Granular nature (morphology, sizes, relationships)
- Textures (trachytic, ophitic, foliations)
- Extinction angles
- Colour

These are features used to identify and group rocks. Quartzite samples were identified and compared by the presence of undulose extinction and Bohm lamellae in addition to the abovementioned features. The presence of interlocking grains, stylolites and syntaxial cement; as well as the shape of grain boundaries (convex-concave), was also used to describe quartzites.

From the studied sample set, 21 samples (12 lithics and nine geological samples, see Table 3.3) were cut in half with a rock cutter at the School of Geosciences (University of the Witwatersrand) for thin sections and ICP-MS powders.

To make the thin sections, the rocks were cut using a diamond saw; embedded in resin, ground flat with corundum 600 and 1200 and water. These were then polished using a polishing machine.

The representative sample of OBP includes the following rock types: dolerite/andesite, shale/meta-sedimentary rocks, white quartzite, black quartzite, red quartzite and quartz. Mwulu's Cave's representative sample includes shale/meta-sedimentary rocks, quartz, black quartzite, white quartzite, and chert (Table 3.5). The rock types analysed are those represented in both the lithic assemblage and the geological assemblage. Chert and quartz samples were not analysed through thin section analysis because no grains would be visible using a microscope. As mentioned, three different types of quartzites (black, white, and red) were selected for the representative sample for grouping, however, red quartzite geologic samples were not found during the prospection survey.

3.2.4 Inductively Coupled Plasma Mass Spectrometry

Inductively Coupled Plasma Mass Spectrometry (ICP-MS) is a highly sensitive element detection analysis. It is also used to quantify elemental concentrations. ICP-MS provides more refined, and accurate, elemental results in comparison to pXRF spectrometry. The error limits for the elements analysed were not provided with the results because the analysis was conducted in the EarthLab (University of the Witwatersrand). This is the final analysis in this project used to identify rocks and link lithics to geological samples.

ICP-MS is reliable because it can detect elements at low detection limits. It also detects multi-element isotopes at high spectral resolutions (Thomas, 2013). This analysis is preferable because, unlike pXRF spectrometry, it can quanitify and detect a larger range of elements, including lighter elements like Na (Thomas, 2013).

Of the 232 samples in this study, 26 underwent ICP-MS preparation and analysis. As shown in Table 3.3, 13 samples from OBP and 13 samples from Mwulu's Cave were analysed using ICP-MS. The samples were prepared using a rock crusher and miller at the School of Geosciences (University of the Witwatersrand) and the powders were sent to the EarthLab (University of the Witwatersrand). They were analysed using a Thermo Scientific iCAP RQ. The Calibration Standards were made at 10, 30, 50, 75 and 100ppb with elements purchased from International Certified Reference Materials (Li, P, Sc, Ti, V, Cr, Co, Ni, Cu, Zn, Ga, Rb, Sr, Y, Zr, Nb, Sn, Sb, Cs, Ba, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Hf, Ta, W, Tl, Pb, U, and Th). From this method, trace element and rare-earth element concentrations were obtained.

3.2.5 Thin Section and Inductive Coupled Plasma Mass Spectrometry Analytical strategy

Only a few representative samples were chosen, based on rock groups that were established through macroscopic analysis, to undergo thin section and ICP-MS analysis to minimise damage to archaeological material (Table 3.4 and Table 3.5). In this table, the localities are given numbers and the samples from each locality are identified using the alphabet (i.e. OBP 8 is the locality and A, B, and C are the samples from that locality).

Table 3.3: Number of lithics and geological samples that underwent each analytical method at OBP and Mwulu's Cave.

	OBP		**Mwulu's Cave**		
Analytical method	**Lithics**	**Geological samples**	**Lithics**	**Outcrops**	**Total**
Macroscopic Analysis	65	48	81	38	232
pXRF	65	48	81	38	232
Thin section petrography	7	5	5	4	21

ICP-MS	8	5	7	6	26

All samples in this project (lithic and geological) were macroscopically and stereomicroscopically analysed. Then they were analysed through pXRF. PXRF was prioritised before making thin sections and performing ICP-MS analyses because it is non-destructive, and it is fast and easy to use on all samples, providing quick preliminary results.

Table 3.4: Number of samples, from each rock type, that underwent destructive analyses. The second and third columns show the total number of lithics and outcrop samples in each rock type from the assemblages of both sites. The fourth and fifth columns show the number of lithics and geological samples that underwent destructive analyses in each rock type (i.e. of the eight dolerite lithics at OBP, 2 underwent destructive analyses). *Chert and altered samples were not analysed further than macroscopic analyses they do not occur in both lithic and outcrop assemblages.

4 RESULTS

4.1 Macroscopic results

The following sections present macroscopic results for each rock type at OBP and Mwulu's Cave. Detailed macroscopic descriptions of OBP and Mwulu's Cave samples are found in APPENDIX A.

4.1.1 OBP and nearby localities' macroscopic rock descriptions

Quartzite

Quartzite is the most abundant raw material used for lithics at OBP (n=28, see Table 3.4). The lithic quartzite from the site, although noted as different colours (white, red, and black), is generally represented by similar macroscopic characteristics such as rounded to sub-angular grains that range from fine-grained (0.1 mm) to coarse-grained (4 mm). The quartzite lithic samples are well-sorted and have annealed or interlocking quartz grains (e.g. No. 143, No. 468; No. 488; No. 2374; No. 3474, No. 2332; No. 2364; No. 2395; No. 1795; YRS1-C; YRS1-E) with minimal visible matrix (roughly 25% based on visual comparison to the amount of grains present in the sample). Generally, the texture of the samples is rough and they have a dull lustre although some annealed samples have a smooth, glassy texture. Because of these common characteristics, they are considered as being part of the same group of quartzite. Six samples from the OBP assemblage (No. 488; No. 1195; No. 488; No. 143; No. 3474; and No. 3478) present a visible cortex (Figure 4.1 A and B). These samples have a brown, orange, and black predominantly dull cortex. These are either smooth or rough. There is no evidence of sedimentary structures in the observed samples.

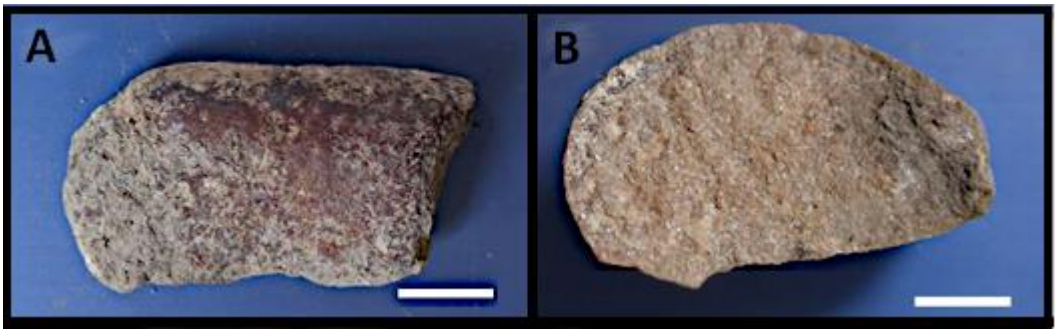

Figure 4.1: A) No. 1195 shows a smooth, red cortical surface. B) No.488 is an image of the white quartzite at OBP. It is also a sample with a cortex. The white bar represents 1 cm.

The reference quartzite collected around OBP is white, black, or red in colour. Two types of quartzite are noted around OBP in the Mogalakwena and the Cleremont Formations. The general characteristics of quartzite from the Mogalakwena Formation include medium to coarse (>3 mm) quartz grains that are sub-rounded to sub-angular and are generally well-sorted. These grains are usually either white, pink-white, or black. This quartzite has a smooth, glassy fresh surface and the grains are interlocked. The quartzite samples from the Cleremont Formation are similar to those from the Mogalakwena Formation although matrix is noted in samples from localities CMF1 and CMF2 (10%). Quartzite pebbles from both the Mogalakwena Formation and the Cleremont Formation have orange, brown, or pinkish brown cortices. These are usually smooth and have a dull lustre. No sedimentary structures are noted in the collected samples.

Shale

Shales are the second most abundant rock type used at this site (n=20, see Table 3.4). Three shale groups are noted at OBP. The shales in the general group are mostly dark coloured (black, red-black, brown) and have a smooth surface and dull lustre. These shale lithics are very fine silt-grained (not visible to the bare eye (Figure 4.2 A)). The second shale group is also dark coloured (brown, black, and grey) and fine-grained although these samples are foliated (e.g. No. 142: Figure 4.2 B). The third group is similar to the previous two groups in terms of colour and grain size, but white, black, or red grain inclusions are present (e.g. No. 106 A2; Figure 4.2 C).

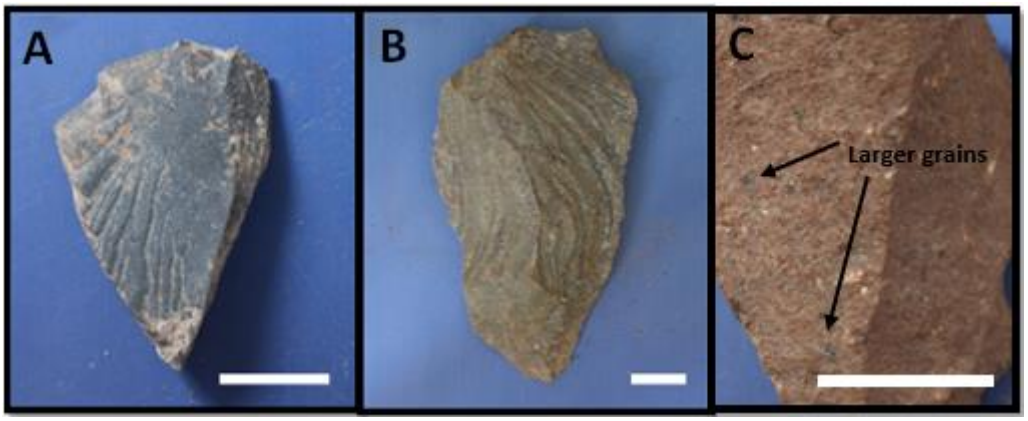

Figure 4.2: A) No. 143 showing fine-grained texture, B) No. 4677 showing foliation (mica minerals are noted along the lighter foliations), and C) No. 106A2 showing larger grain inclusions. The white bar represents 1 cm.

Only one shale locality was noted around OBP. The shales sampled from OBP 10 are very fine-grained (grains cannot be seen with the naked eye) and black in colour. They are smooth to touch and have a dull lustre. OBP 10B has a foliation noted on its edges.

Sandstone

Generally, two sandstone groups are noted in the OBP lithic assemblage. The first is the general group and the second branches off the general group due to the presence of quartz phenoclasts (No. 2402; Figure 4.3 A, and No. 1194). The sandstone lithics (n=6, see Table 3.4) in both groups are light brown, red, and/or black in colour. They have rough textures and dull lustres (No. 1286; Figure 4.3 B) with the exception of No. 1194 (smooth texture) and No. 2366 (glassy lustre Figure 4.3 C). The quartz grains in the OBP lithic sandstones range from medium to coarse (0.4-1.5 mm) and they show a range of grain shapes (angular to sub-rounded). The quartz grains are well-sorted, and the matrix percentage is low (≤10%). Sedimentary structures are not visible due to the small size of the lithics.

Figure 4.3: A) No. 2402 showing a coarse-grained texture and quartz phenoclasts. B) No. 1286 and C) No. 2366 are examples of the general characteristics of OBP sandstone lithics. The white bar represents 1 cm.

Samples OBP 3C, OBP 7, OBP 8A, OBP 8B, and OBP 8C are sandstones collected around the shelter (OBP 8 is a large outcrop and the divisions are based on the layers). Three sandstone groups are noted around OBP. Generally, all the sandstones are red or black. They have a rough and dull brown weathered surface with a glassy fresh surface. The grains are coarse (0.7-5 mm), sub-rounded to sub-angular, and they are well-sorted. A group is formed by OBP 3C and OBP 8A because they are banded and have fine oxidised layers (grains: 0.5 mm). OBP 8B and OBP 8C form another group because they are friable sandstones (sandstones sensu stricto). Matrix is only clearly noted in OBP 8C.

Dolerite

No. 182; No. 1241; No. 130; No. 408; No. 458; No. 489; No. 4672; and No. 4688 (n=8, see Table 3.4) are dolerites. These are aphanitic to medium-grained and have scattered white plagioclase laths (up to 1 mm long) in black matrices (Figure 4.4). They have a smooth texture and a dull lustre.

Figure 4.4: No. 1241 shows the medium-grained texture of OBP dolerite samples and fine plagioclase laths. This sample is coated in calcium carbonate. The white bar represents 1 cm.

Ex situ dolerite around OBP is aphanitic and has a brown weathered surface and a black, fresh surface (OBP 4G; OBP 5A, D and, E). Plagioclase laths are only visible in OBP 5D (~10%).

Quartz

No. 493 (pink) and No. 1290 (pink-white) are the only two quartz (monocrystalline) samples noted in OBP lithics (Figure 4.5). They both have smooth fresh surfaces although No. 493 has a dull lustre and No. 1290 has a glassy one.

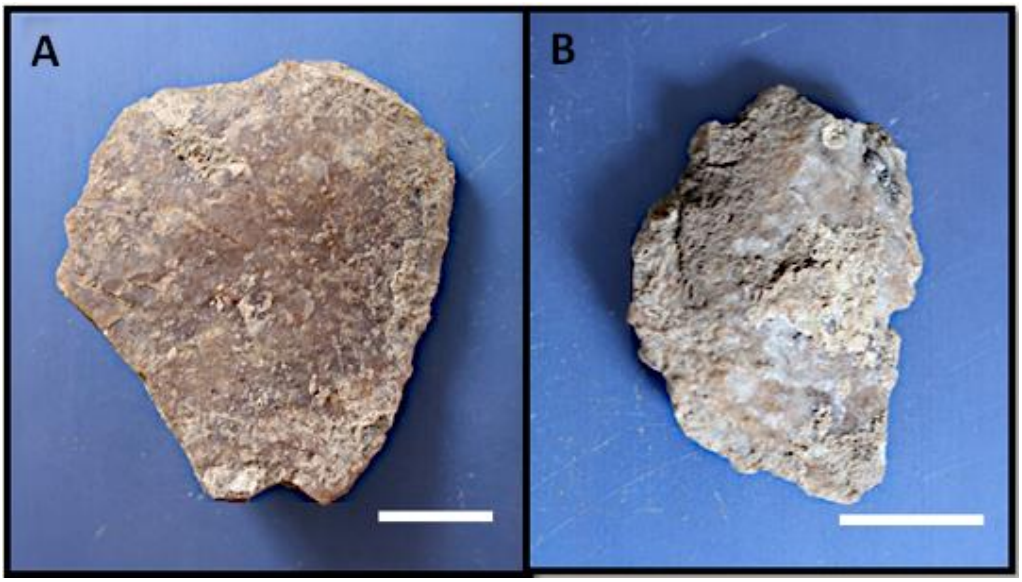

Figure 4.5: A) No. 493 and B) No.1290 showing their colours, surface textures and lustres. The white bar represents 1 cm.

Most quartz samples are generally pink-white (like the pebbles) but vein quartz, like that sampled at OBP 4D, is pure white. Unlike quartzite pebbles, quartz pebbles have a more pitted and striated cortical surface.

Chert

Very fine-grained, cream white chert (No. 412) also forms part of the OBP lithic assemblage (Figure 4.6). This sample will not be analysed through any other methods because no chert sources could be sampled near OBP.

Figure 4.6: Image of the only chert in the OBP assemblage, No. 412. The white bar represents 1 cm.

4.1.2 Mwulu's Cave lithic macroscopic descriptions

Quartzite

The majority of Mwulu's Cave lithics are quartzite (n=52, see Table 3.4). These are generally either white or black in colour although M3-C is a red quartzite. Three quartzite groups are recognised in this assemblage. These are the general group, the quartzite with pore spaces, and the plane bedded quartzite. Generally, samples have dull, smooth textures while others are rough to the touch. Grain sizes throughout the assemblage range from fine (0.1 mm) to coarse (1 mm). Quartz grains are rounded, sub-rounded, or sub-angular depending on the sample. They are also predominantly interlocked (crystal boundaries touching) or annealed (crystals recrystallised to form larger grains) although annealing is more prominent in black quartzite samples. The grains in the quartzite lithics are well-sorted and have minimal matrix. The lithics in the first group to branch off the general group have pore spaces throughout them (e.g. M1-B; Figure 4.7 A). The second group to branch off the general group has grey and white plane beds as noted in No. 673 (Figure 4.7 B). There is no evidence of other sedimentary structures in the observed samples.

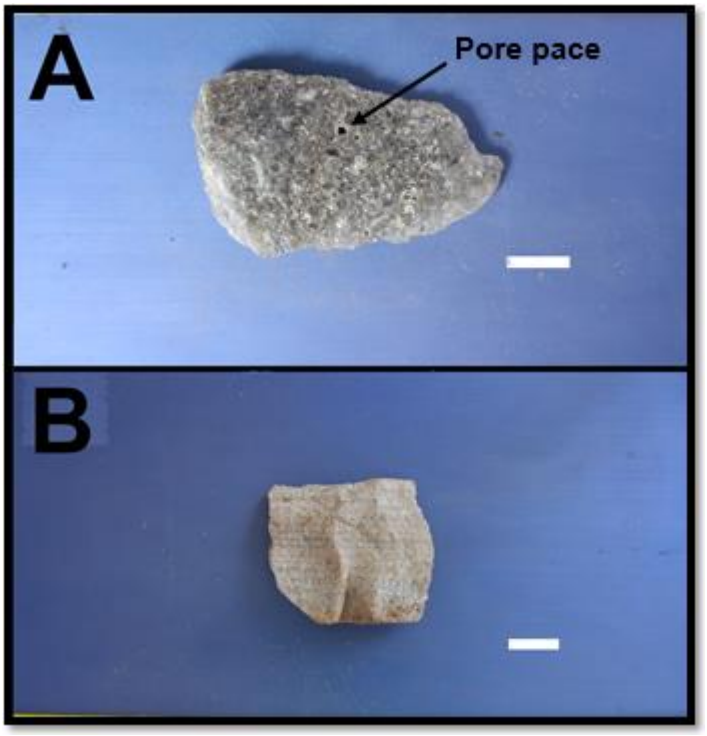

Figure 4.7: A) M1-B shows annealed texture and pore spaces. B) Plane beds are shown in No.673. The white bar represents 1 cm.

Generally, quartzite around Mwulu's Cave is either a variation of white or black (white-grey-black spectrum). This colour distinction has no influence/effect on the kinds of characteristics found in a quartzite. They all have a rough orange or brown weathered surface and a dull texture. The quartzite is coarse-grained (>5 mm) with sub-rounded to sub-angular quartz grains. The samples are well-sorted (minimal matrix) and have interlocking grains. Plane bedded quartzite around Mwulu's Cave occurs as Outcrop 17 (white and grey) and Outcrop G2B.

Shale

The shale in this lithic assemblage (n=10, see Table 3.4) is dark in colour and its lustre is dull on the weathered surface and shiny on the fresh surface. It is very fine-grained (Figure 4.8). There is no evidence of sedimentary structures in the observed samples.

Figure 4.8: M3-E showing the dark colour and fine-grained texture of Mwulu's Cave shale. The white bar represents 1 cm.

The shale around Mwulu's Cave forms part of the BRQF, the Duitchsland Formation and the Malmani Subgroup. Generally, the shales are dark coloured (grey, black, and brown) and their weathered surface is grey and/or red-orange in colour. They have a smooth texture and a dull lustre. They are also very fine-grained. Some BRQF shale samples are bedded and mica (gold-brown) is noted along these bedding planes. The only noted difference between shales from the remaining formations is that the Malmani Subgroup shales are generally darker (dark grey and black) than those from the Duitschland Formation (green-grey and brown).

Quartz

Eleven quartz samples form part of the lithic assemblage at Mwulu's Cave (Table 3.4). Two types of quartz are noted at this site, fresh white vein quartz and weathered, iron-stained quartz (Figure 4.9). The white quartz is smooth to tough and has a glassy lustre. It also has orange staining along its cracks. The translucent quartz (No. 2073) is matte, has a grainy texture and a dull lustre.

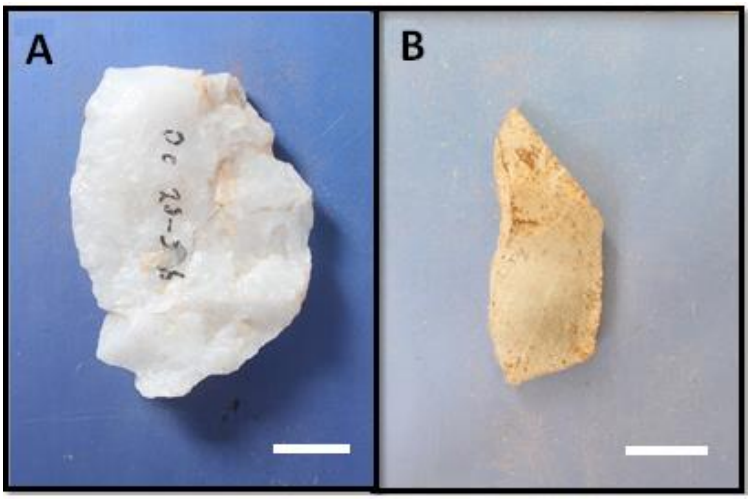

Figure 4.9: A) M1-F is white and has a glassy lustre. Orange staining is seen along the cracks. B) No.2073 is a weathered quartz sample with iron-staining. The white bar represents 1 cm.

Quartz outcrop samples (xenomorphic: lacking its characteristic crystal shape) are either light grey (Outcrop 16B), white (Outcrop 19A), or white and red (Outcrop 20). These samples are smooth and glassy. At the cave, automorphic quartz (presenting its characteristic crystal shape) was also sampled in a little cave besides Mwulu's Cave (Outcrop 16F).

Chert

The three chert samples (Table 3.4) in this assemblage are grey and very fine-grained (M1-K; No. 674; PALO49). They are smooth to touch and have a dull lustre. They are also banded (grey and dark grey) (Figure 4.10).

Figure 4.10: A) M1-K and No. 674 showing grey banding. The white bar represents 1 cm.

Chert is regularly seen interbedded with the Malmani dolomite. It is grey and has a red or brown weathered surface. It has a smooth texture and a dull lustre. The chert samples collected around Mwulu's are very fine-grained (grains are not visible to the naked eye).

Taphonomically Altered samples

Some lithic samples made of taphonomically altered rock types (will just be written as 'altered' throughout the text) also form part of Mwulu's Cave lithics (M1-E; M1-G; M2-B (Figure 4.11); M2-C (Figure 4.11); PA-11). These have pore spaces throughout them. They will not be analysed further because their rock type is difficult to establish due to the alteration and therefore no possible source outcrops can be determined.

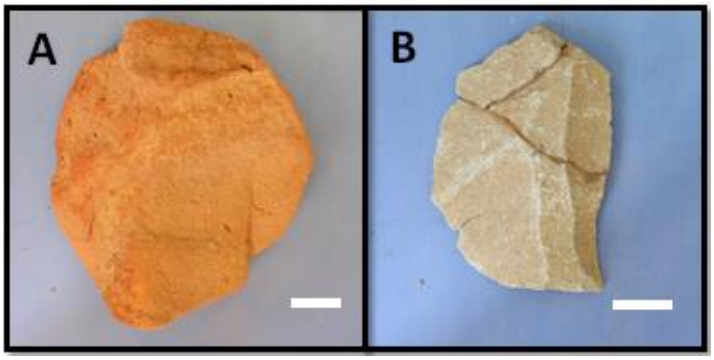

Figure 4.11: A) M2-B and M2-C showing the altered samples. The white bar represents 1 cm.

4.2 Portable X-ray fluorescence Results

As shown in the materials and methods section, lithics from OBP were divided into five rock types and those from Mwulu's Cave into four rock types. All the lithics and geological samples were analysed using pXRF to provide preliminary provenance possibilities. The results are shown in principal component analysis plots ('PCA'; multivariate analysis) and scatterplots below. The full pXRF raw data can be found in APPENDIX B.

4.2.1 Olieboomspoort Rock Shelter Portable X-ray Fluorescence data

Olieboomspoort Rock Shelter Scatterplots

Quartzite

After screening several reference materials scatterplots, it appeared that scatterplots Ti/Fe and Si/Al were the most useful to discriminate the reference outcrops. Samples collected from secondary contexts nearby Cleremont Formation all have an Fe content under 1.0% and a Ti content over 700 ppm (Figure 4.12 A). Samples collected from secondary contexts nearby Mogalakwena Formation appear to be more diverse but present higher Fe content. Two localities (OBP 1 and OBP 4) are very different from the rest of the samples collected nearby the Mogalakwena Formation because they have higher Fe content than the rest. From the Si/Al scatterplot (Figure 4.12 B) it is evident that all samples close to the Cleremont Formation have an Al content above 1.1% and an Si content between 32.0% and 44.6%. The *in situ* Cleremont Formation outcrop samples, in particular, have a higher Al content than the secondary samples. Similar to the Ti/Fe scatterplot, the Si/Al scatterplot shows that samples collected from secondary contexts near the Mogalakwena Formation are more diverse than those near the Cleremont Formation. They present higher Al content and lower Si content in comparison to the Cleremont Formation samples. It is observed that some Mogalakwena Formation and Cleremont Formation samples overlap (OBP 6B and BPC1F, and CMF1,

OBP 4E, and OBP 6A). Among these overlapping geological samples, CMF1 is the only *in situ* quartzite.

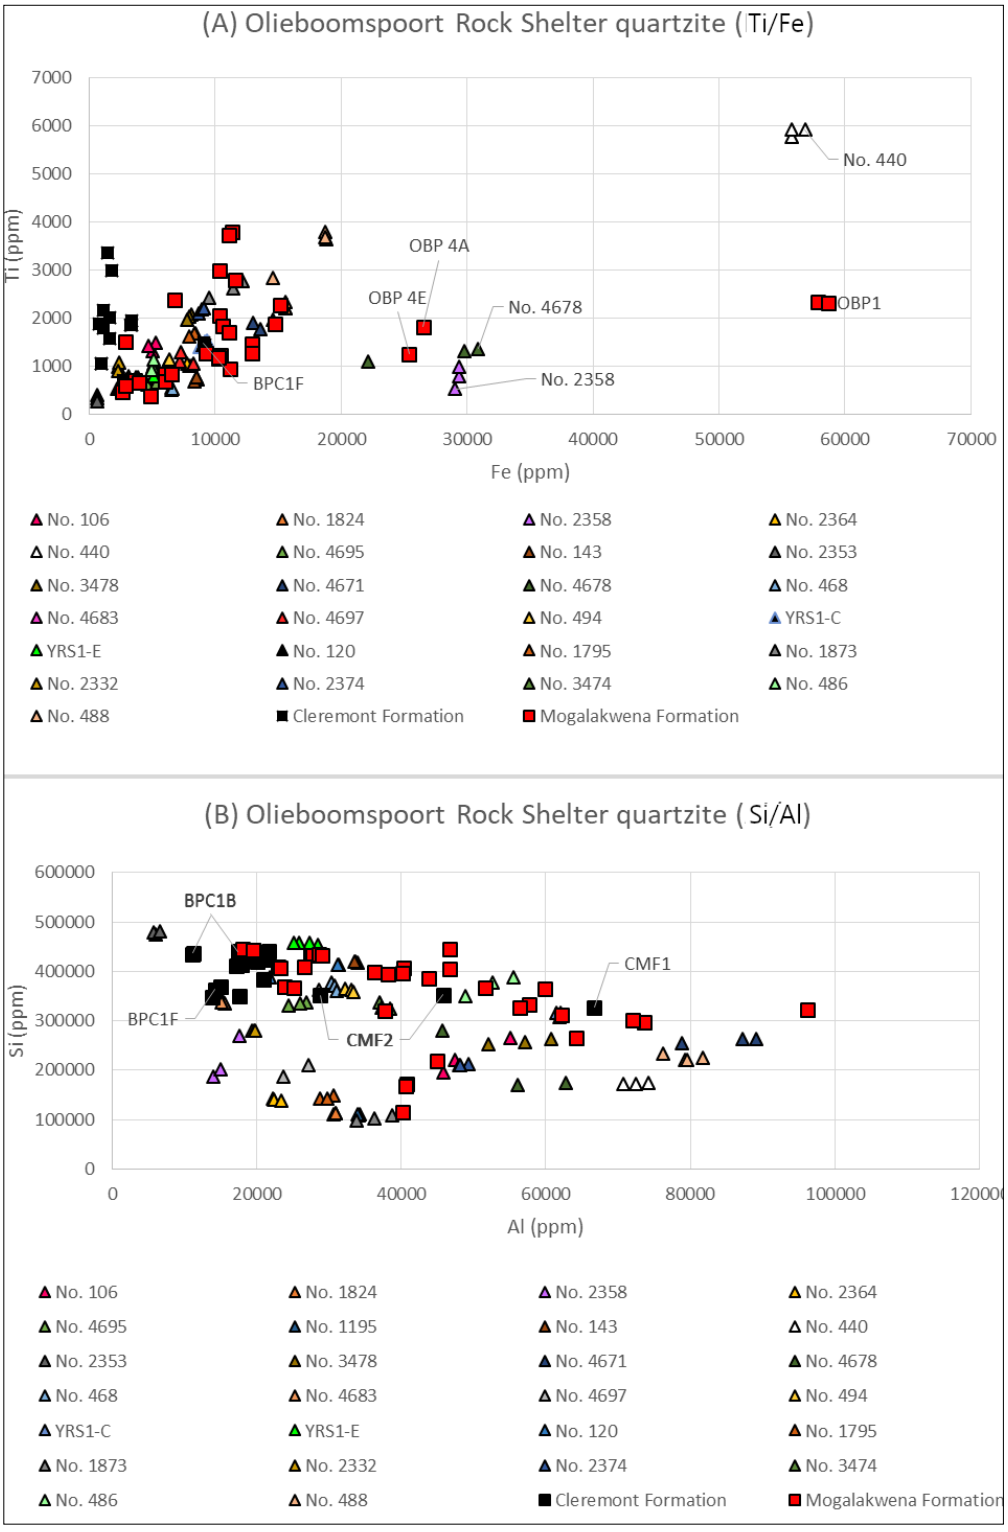

Figure 4.12: A) Ti/Fe scatterplot of quartzite samples at OBP. B) Si/Al scatterplot of quartzite samples at OBP.

Shale

Scatterplot K/Al (Figure 4.13) shows that shale samples collected in secondary context around the Mogalakwena Formation have an Al content between 1.9% and 11.0%. The K content of these samples is below 9500 ppm. Secondary sample OBP 10B has an Al content that is significantly higher than that of OBP 10A.

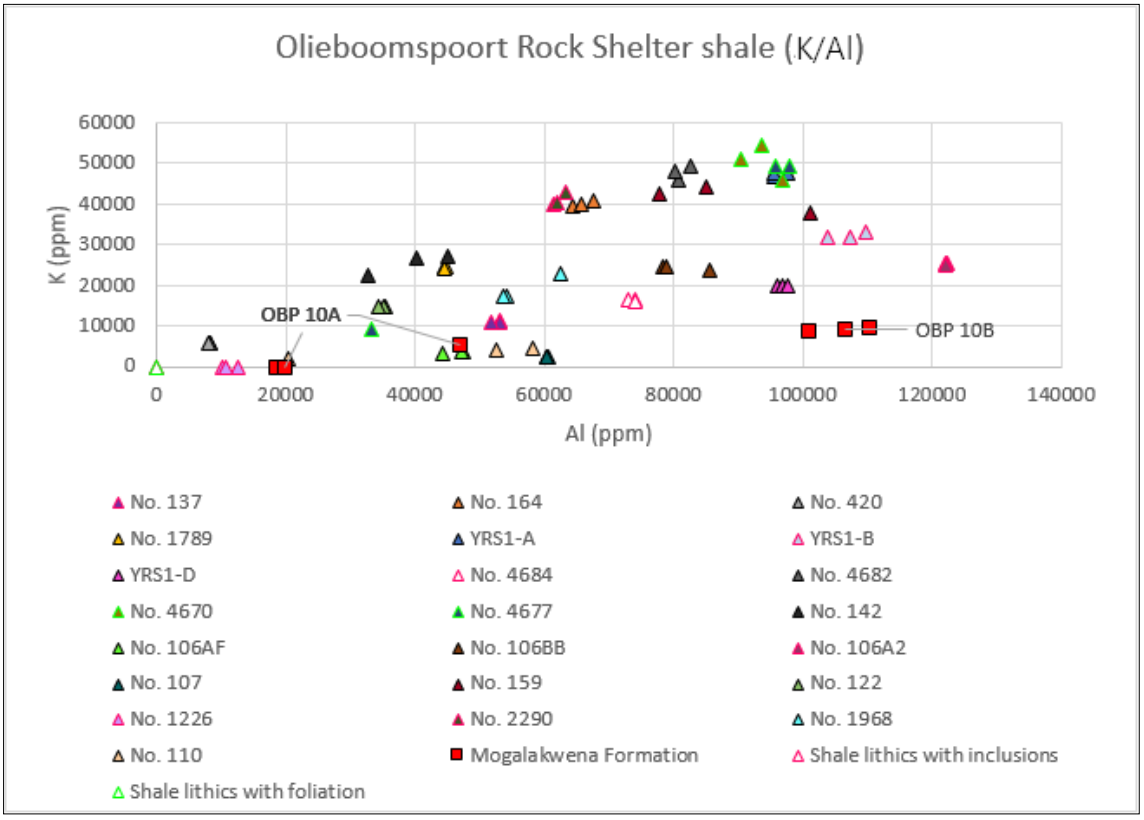

Figure 4.13: A) K/Al scatterplot showing shale samples at OBP.

Sandstone

The most useful scatterplots to discriminate OBP sandstone samples were Ti/Fe (Figure 4.14 A), and Si/Al (Figure 4.14 B). The secondary context sandstone samples collected around the Mogalakwena Formation have a Fe content below 3% and a Ti content below 2400 ppm. Their Al content lies between 2.8% and 7.6% while their Si content is over 18.6%.

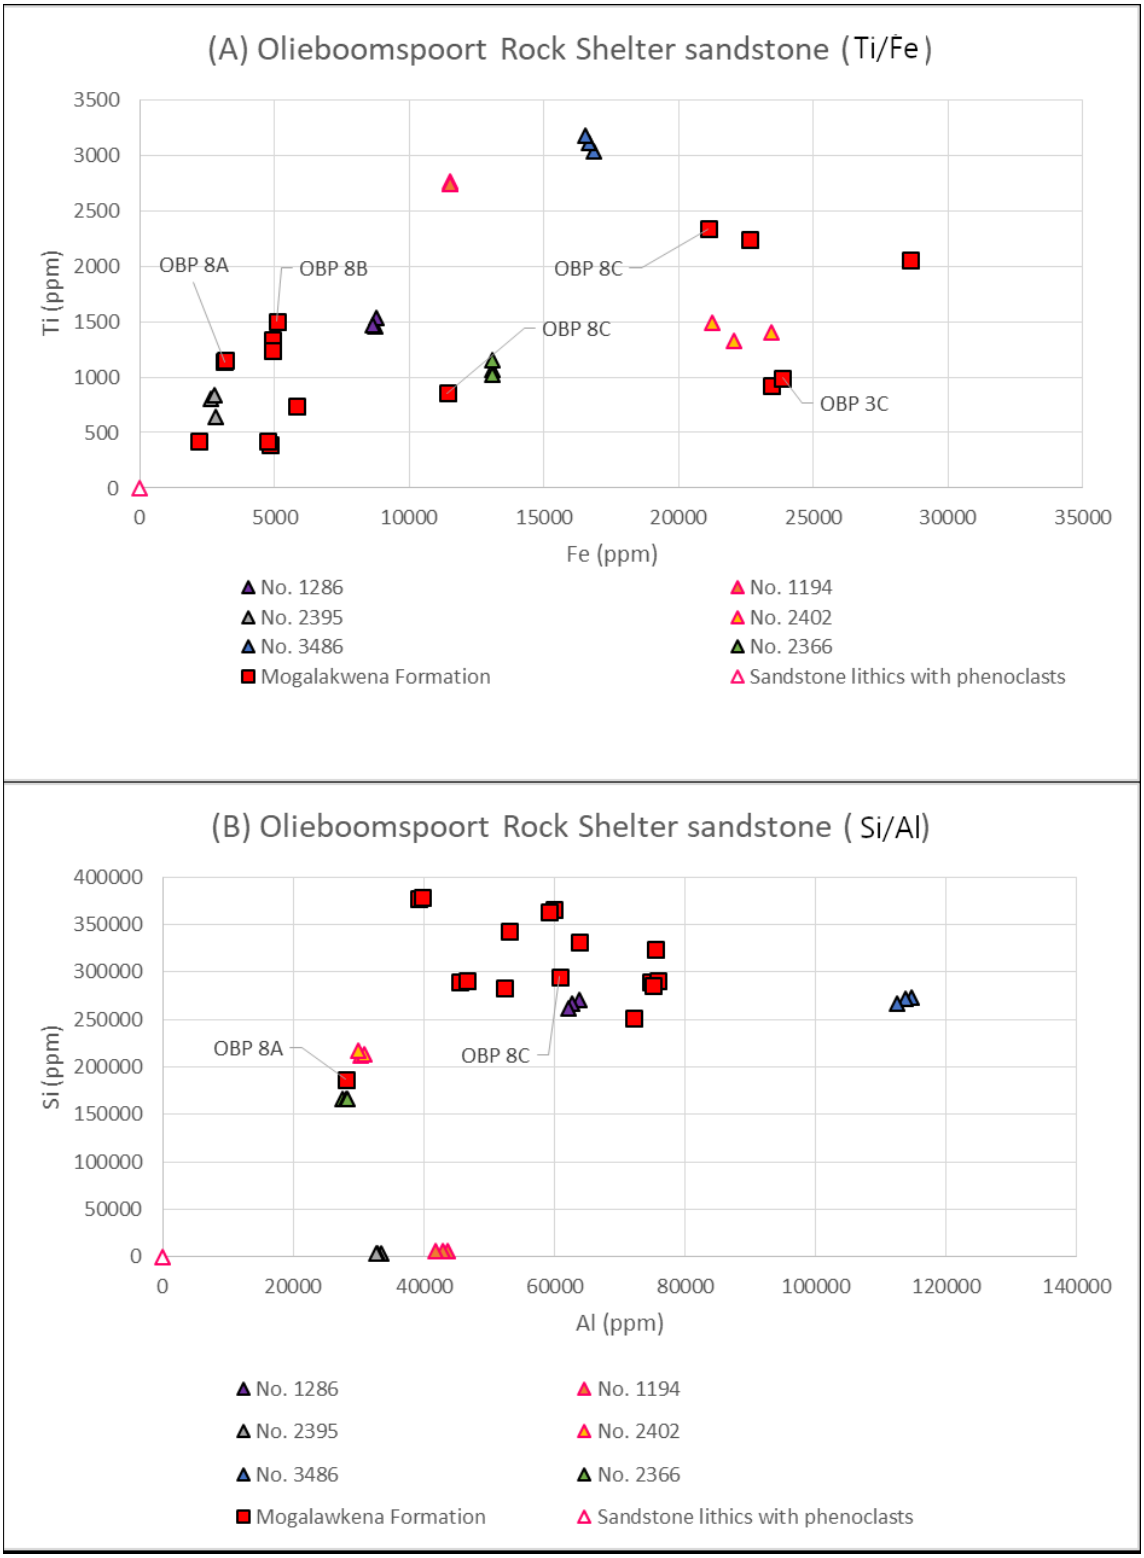

Figure 4.14: A) Ti/Fe scatterplot of sandstone samples at OBP. B) Si/Al scatterplot of sandstone samples at OBP.

Dolerite

Scatterplots Ti/Fe (Figure 4.15 A) and Si/Al (Figure 4.15 B) are the most informative when it comes to comparing OBP dolerite samples. The reference samples collected in secondary contexts around the Mogalakwena Formation have a Fe content between 12.1% and 15.9% and a Ti content between 1.5% and 1.8%. The Al content of these samples is between 7.4% and 12.5%, and the Si content is between 20.2% and 28.7%. *Ex situ* sample OBP 5A plots outside of the Ti range (1.1%) and the Si range (16.5%).

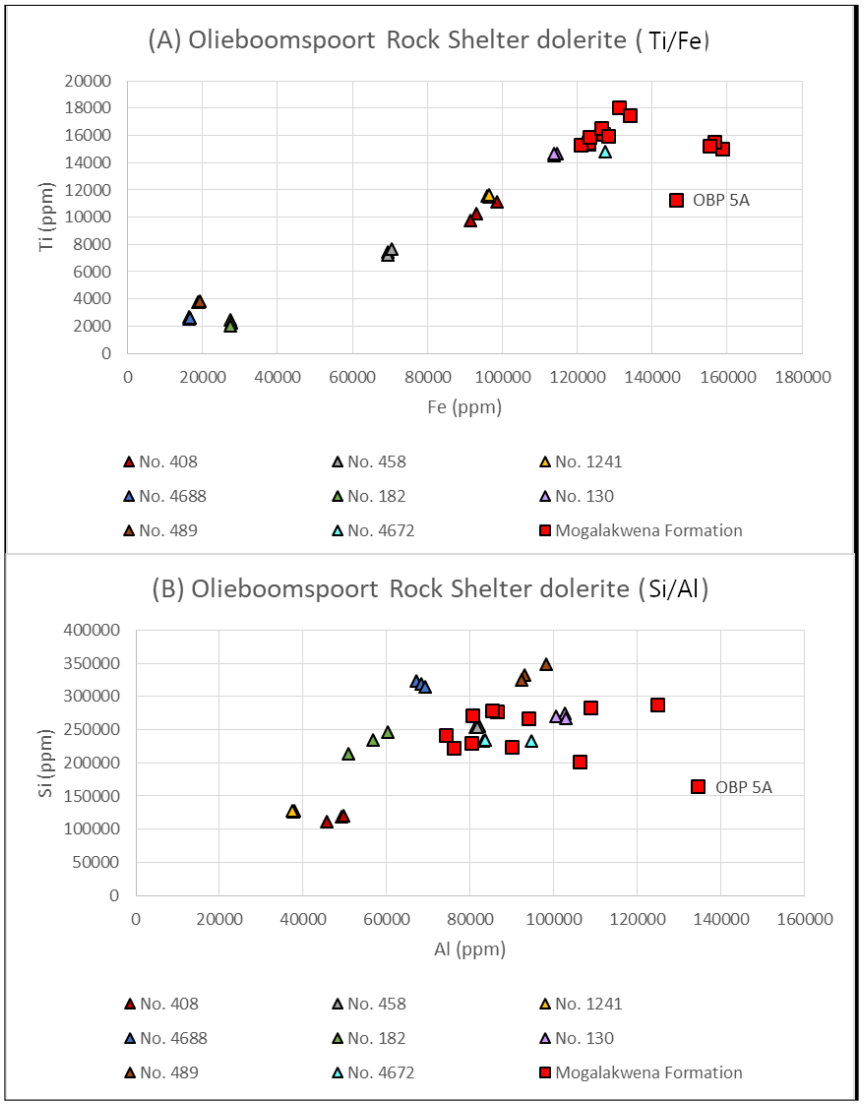

Figure 4.15: A) Ti/Fe scatterplot of dolerite samples at OBP. B) Si/Al scatterplot of dolerite samples at OBP.

Quartz

The Ti/Fe (Figure 4.16 A) and Si/Al (Figure 4.16 B) scatterplots are the most useful graphs for making comparisons between geological samples from the Cleremont Formation and those from the Mogalakwena Formation. Samples from both formations plot very close to one another. The Fe content in the geological samples collected around the Cleremont Formation is less than 4000 ppm and the Ti content is less than 1880 ppm. The Al content of these samples ranges from 1.8% to 3.1% while the Si content ranges from 38.3% to 43.4%. The geological samples collected around the Mogalakwena Formation are more diverse in both scatterplots and generally have higher Fe and Ti contents, as well as Al and Si contents, compared to the Cleremont Formation samples.

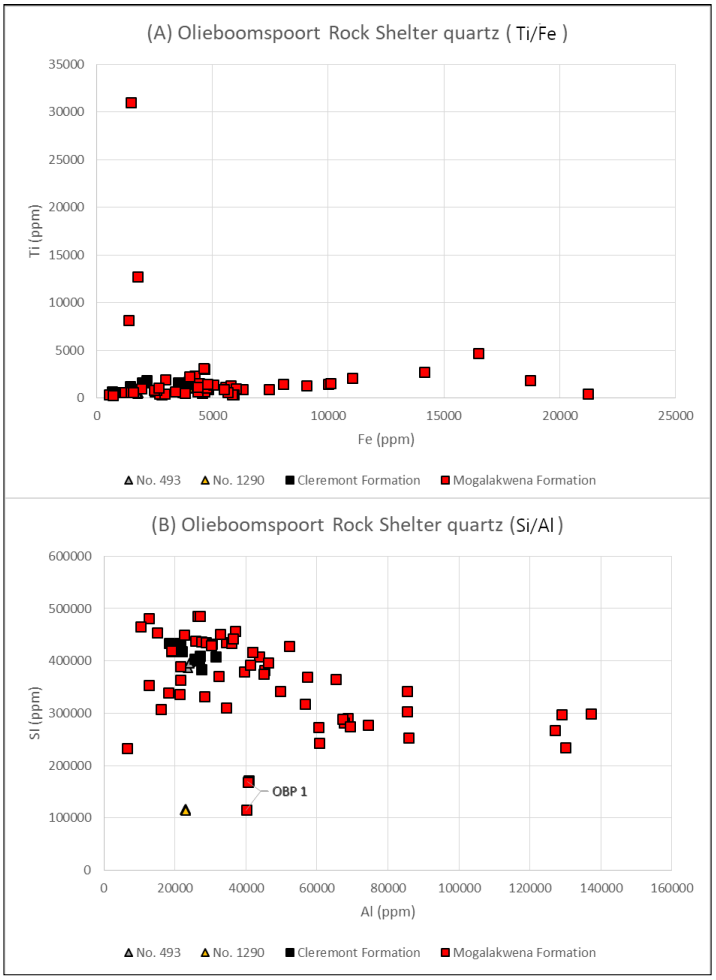

Figure 4.16: A) Ti/Fe scatterplot of quartz samples at OBP. B) Si/Al scatterplot of quartz samples at OBP.

Principal Component Analysis of Olieboomspoort Rock Shelter Samples

A total of 48 geological source samples and 65 lithics from around OBP were analysed through pXRF in this project. The results of this analysis were used to differentiate between the different rock types found around the site, and to to see how lithics grouped with the rock types and different foramtions within these rock types. The following elements were used in different PCA plots for this purpose: Al, Si, S, K, Ti, V, Cr, Mn, Cu, Zn, Fe, Ni, RB, Sr, Y, Zr, Nb, Pb, and Th. In all of the following biplots, the first two principle components are plotted. The PCA results are given below and tables with the element coordinates for PC1 and PC2 can be found in Appendix B.

Differentiation of Rock Types

In Figure 4.17, PC1 and PC2 show 61.6% of the total variation obtained through using elements Al, Si, S, Ti, V, Cr, Mn, and Fe. The best projected elements on PC1 (47.5% variation) are Fe, Mn, and V. The best projected elements on PC2 (14.1% variation) are S, Cr, and Si.

Two distinct groups are noted from the Rock Types PCA plot. One with dolerite, and the other with quartzite, quartz, sandstone, and shale. There is less variability in elements best projected by PC2 (S, Cr, and Si) across the different rock types in comparison to those best projected by PC1 (Fe, Mn, and V). Dolerite is richer in Fe, Mn, and V in comparison to quartzite, quartz, sandstone, and shale as seen on the PC1 axis. It can be clearly distinguished from the rest of the OBP rock types. All the rock types, with the exception of dolerite, overlap their 80% significance level ellipses (fill) and their 95% significance ellipses (dash). These rock types cannot be well differentiated from one another based on this plot.

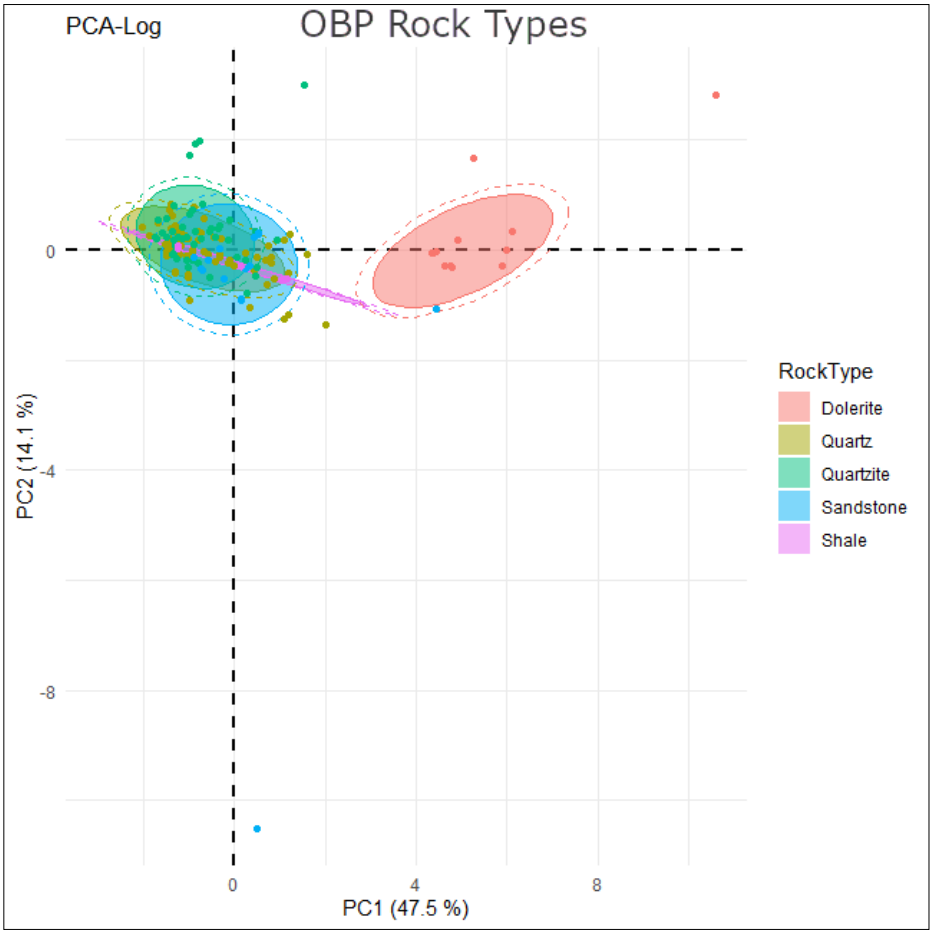

Figure 4.17: The PCA of overlapping OBP rock types (except dolerite) from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash).

PCA plots of OBP quartzite samples

In the 'Quartzite Formations' PCA plot, PC1 and PC2 show 53.9% of the total variation (Figure 4.18A). These variations were obtained by using elements Al, Si, Ti, Mn, Fe, Rb, Sr, Y, and Zr. The best projected elements for the quartzite formations on PC1 (35.2% variation) are Si, Fe, Mn and those on PC2 (18.7% variation) are Y, Rb, and Zr.

The Mogalakwena Fm and Cleremont Fm geological samples cannot be differentiated from each other using this plot. Instead the Mogalakwena Fm samples enclose the Cleremont Fm samples with a 100% overlap of its 80% significance level ellipse. The Mogalakwena Fm is more diverse in elements best projected by PC1 and PC2 compared to the Cleremont Fm. Because these formations are overlapping, it is difficult to determine to which the quartzite lithics belong.

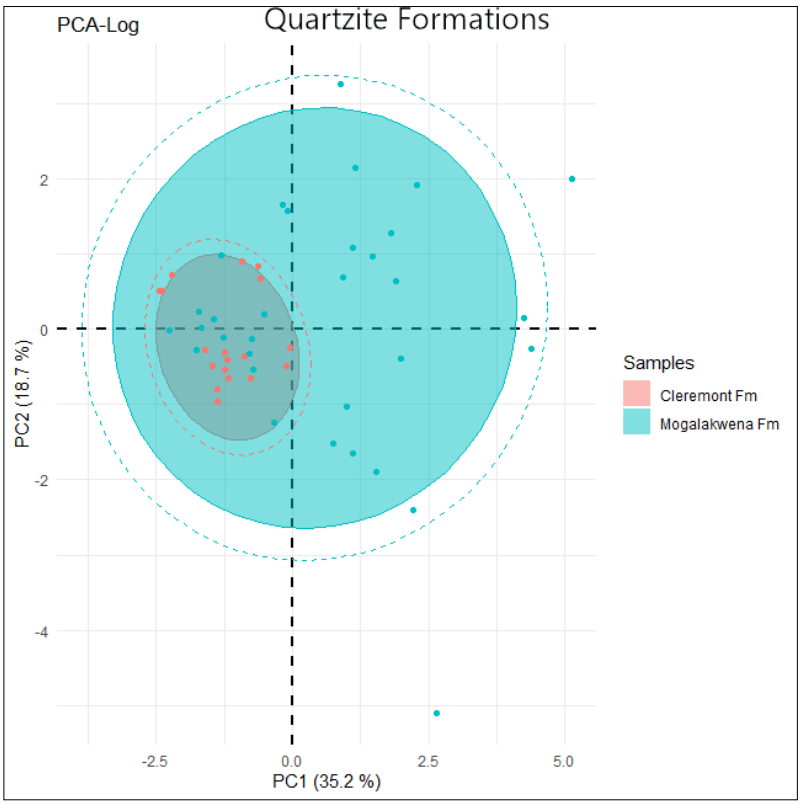

Figure 4.18: The PCA of overlapping OBP quartzite formations from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash).

PCA plot of all the OBP shale samples

Only one formation could be studies for shale around OBP. In the ‘ All shale samples’ (outcrops and archaeological samples) PCA plot (Figure 4.19), PC1 and PC2 show 56.4% of the total variation obtained through using elements Al, Si, P, S, K, Ti, V, Mn, Fe, Zn, Rb, Sr, Y, Zr, Nb, and Pb. The best projected elements on PC1 (34.5% variation) are Zr, Nb, and Y. The best projected elements on PC2 (21.9% variation) are S, Zn, and K.

None of the shale lithics, with the exception of No. 420, lie within the the 80% significance level ellipse of the Mogalakwena Fm samples. Instead the lithic assemblage is more diverse along the PC2 axis. This is because insufficient shale geological samples were able to be collected.

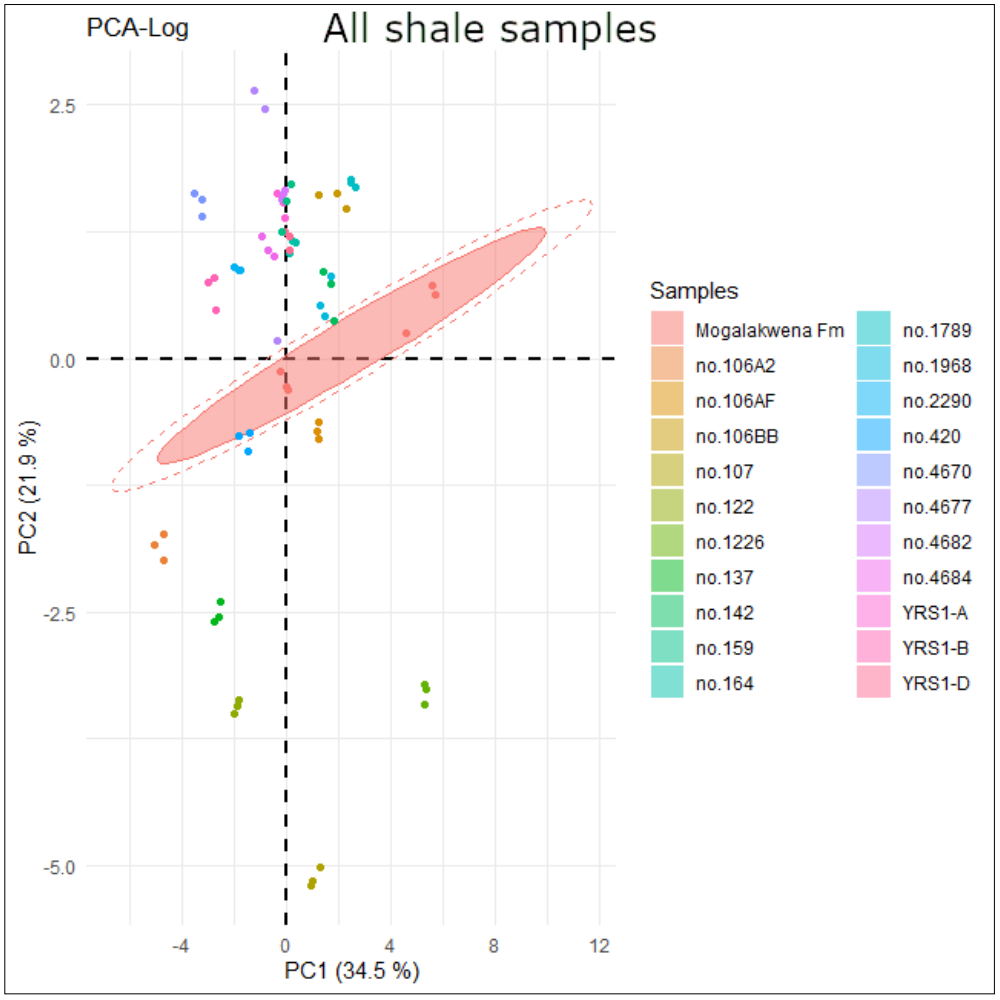

Figure 4.19: The PCA of OBP shale samples from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash). It shows the unrelatedness of Mogalakwena Fm samples and the lithics.

PCA plot of sandstone samples

Onlys sandstones from one formation (Mogalakwena Fm) were analysed in this study. In the 'All sandstone samples' (outcrops and archaeological samples) PCA plot (Figure 4.20), PC1 and PC2 account for 57.3% of the total variation obtained through using elements Al, Si, S, K, Ti, V, Mn, Fe, Cu, Zn, Rb, Sr, Y, and Zr. The best projected elements on PC1 (35.2% variation) are Zn, Zr, and V. The best projected elements on PC2 (22.1% variation) are K, Y, and Rb.

All the OBP sanstone lithics fall within the Mogalakwena Fm 80% significance level ellipse except for No. 1194. No. 1194 is richer in Zn, Zr, and V compared to the rest of

the lithics and the geological samples From the Mogalakwena Fm. For this reason, its provenance cannot be determined.

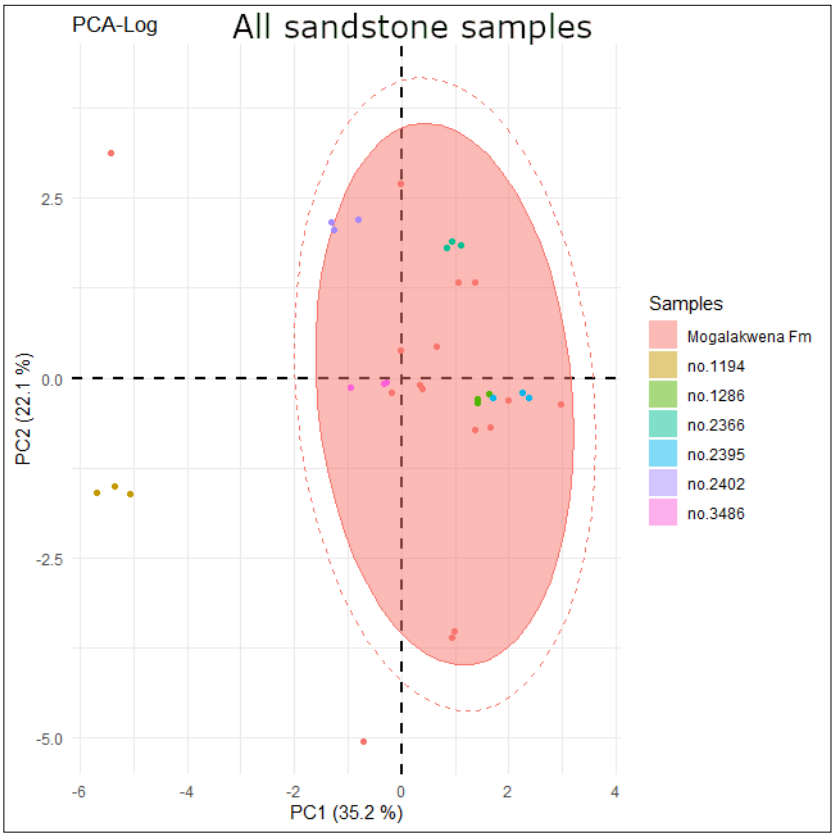

Figure 4.20: The PCA of OBP sandstone samples from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash). Most lithics fall within the ellipse of the Mogalakwena Fm samples.

PCA plot of all the OBP dolerite samples

Only dolerites from the Mogalakwena Fm could be analysed in this study. In the ‘ All dolerite samples’ (outcrops and archaeological samples) PCA plot (Figure 4.21), PC1 and PC2 show 50.5% of the total variation obtained through using elements Al, Si, P, S, Ti, V, Mn, Fe, Ni, Zn, Rb, Sr, Y, and Zr. The best projected elements on PC1 (36.2% variation) are Fe, Ti, and Rb. The best projected elements on PC2 (14.3% variation) are P, Si, and Al.

From this PCA plot, it is noted that the majority of the lithics are not similar to the dolerite geological samples collected from the Mogalakwena Fm. Only No. 130 lies

slightly on the 80% significance level ellipse of this formation. No. 458, No. 182, No. 4688, and No. 489 are poorer in Fe and Ti, and richer in Rb compared to Mogalakwena shale geological samples. No. 4672, No. 408, and No. 1241 are richer in P and poorer in Si and Al compared to the Mogalakwena shale geological samples. Based on these results it is difficult to determine the provenance of most OBP dolerite lithics.

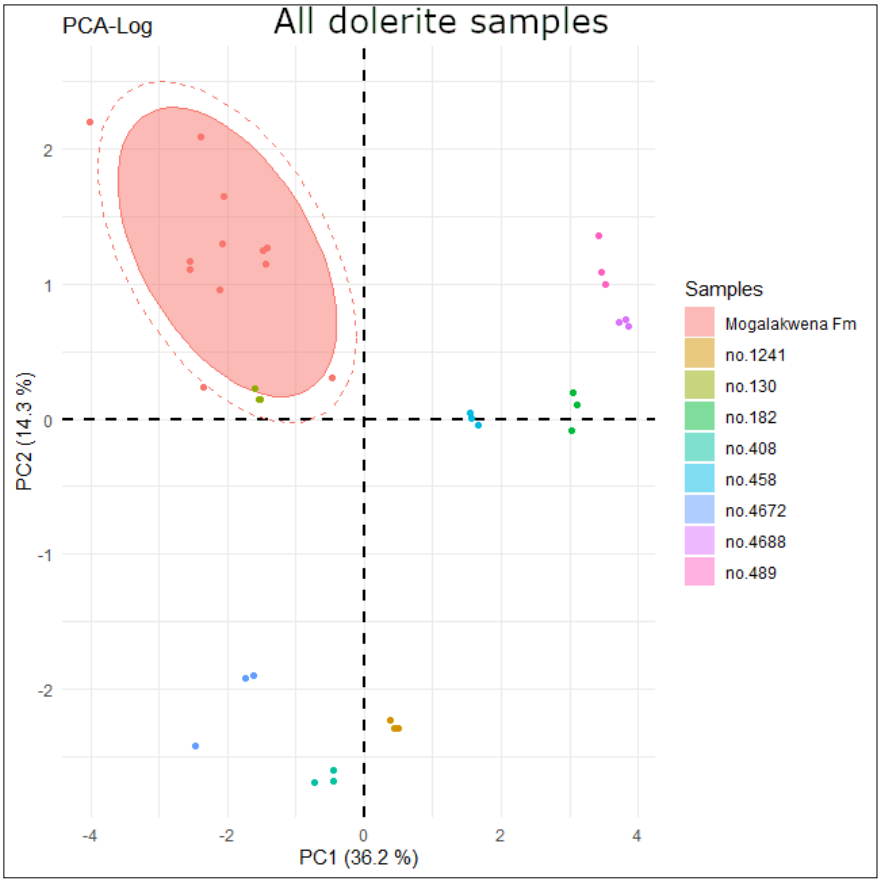

Figure 4.21: The PCA of OBP dolerite samples from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash). It shows the disparity between Mogalakwena Fm samples and the lithcs.

PCA plots of OBP quartz samples

In the 'Quartz Formations' PCA plot, PC1 and PC2 show 58.9% of the total variation (Figue 4.22). These variations were obtained by using elements Al, Si, S, Ti, V, Cr, Mn, and Fe. The best projected elements for quartz formations on PC1 (33.6% variation) are Fe, Mn, and Si and those on PC2 (25.3% variation) are V, Ti, and Al.

The Mogalakwena Fm and Cleremont Fm geological samples cannot be differentiated from each other using this plot. Instead the Mogalakwena Fm samples enclose the Cleremont Fm samples with a 100% overlap of its 80% significance level ellipse, similar to the quartzite geological samples. The Mogalakwena Fm, however, is more diverse in elements best projected by PC1 and PC2 compared to the Cleremont Fm. Due to this overlap, it is difficult to determine the provenance of the quartz lithics from OBP.

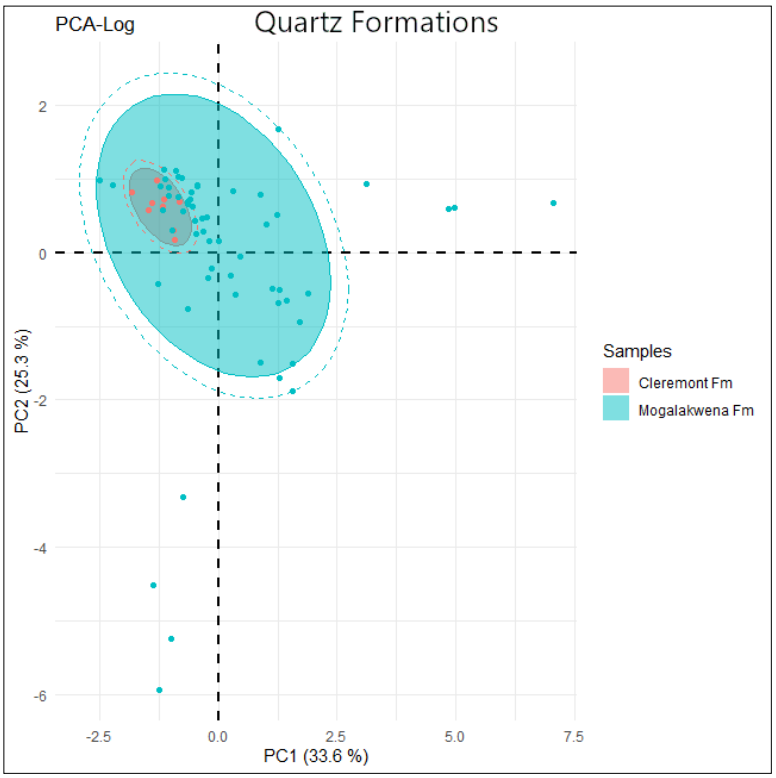

Figure 4.22: The PCA of overlapping OBP quartz formations from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash).

4.2.2 Mwulu's Cave Portable X-ray Fluorescence data

Mwulu's Cave Scatterplots

Quartzite

After screening the scatterplots of the reference materials, the most informative scatterplots to compare Mwulu's Cave samples were Ti/Fe (Figure 4.23 A) and Si/Al (Figure 4.23 B). Generally, the outcrop samples collected around the BRQF have a Fe

content below 5100 ppm although some samples have a higher Fe content (e.g. Outcrop 16A: 1.8%). The Ti content of most outcrop samples collected from the BRQF is below 5800 ppm but that of Outcrop 19B is much higher (2.3%). These outcrop samples have an Al content below 6.9% and a Si content that ranges between 21.9% and 42.5%.

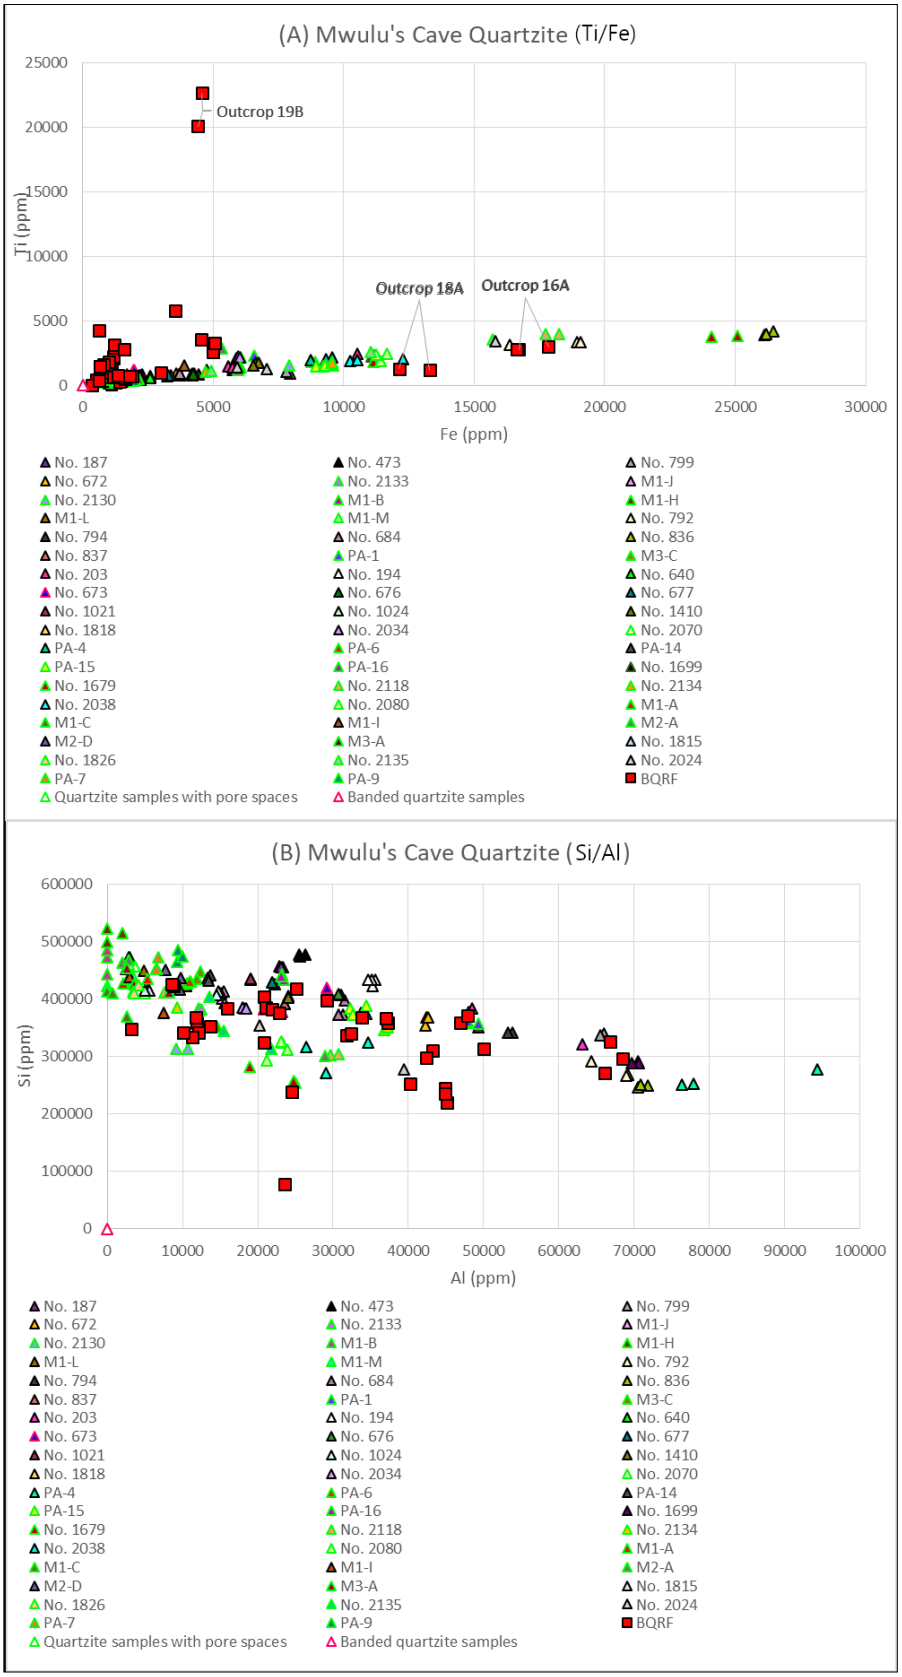

Figure 4.23: A) Ti/Fe scatterplot of quartzite samples at Mwulu's Cave. B) Si/Al scatterplot of quartzite samples at Mwulu's Cave.

Shale

The K/Al (Figure 4.24 A) and Zr/K (Figure 4.24 B) scatterplots offered the most useful results to discriminate the geological samples collected around the BRQF, the Duitschland Formation and the Malmani Subgroup. The shale outcrop samples collected from the BRQF have an Al content that ranges between 6% and 15.8%, and a K content from 1.1% to 4.5%. The outcrop samples collected from the Duitschland Formation generally have lower K/Al ratios than those from the BRQF. The Malmani Subgroup geological samples are more diverse than those from BRQF and the Duitschland Formation. They also have higher K contents compared to those from the BRQF and the Duitschland Formation. In terms of Zr/K ratios, all the outcrop samples collected from the BRQF have a K content below 4.3% and a Zr content over 130 ppm. The Zr content in these BRQF samples is more diverse than in the Duitschland Formation and the Malmani Subgroup. Outcrop samples collected from the Duitschland Formation are concentrated between 2725 ppm and 1.2% K content while a Zr content between 32 ppm and 123 ppm is noted. The Malmani Subgroup geological samples have a more diverse and higher K content than both the BRQF and Duitschland Formation samples, and they have a Zr content below 170 ppm.

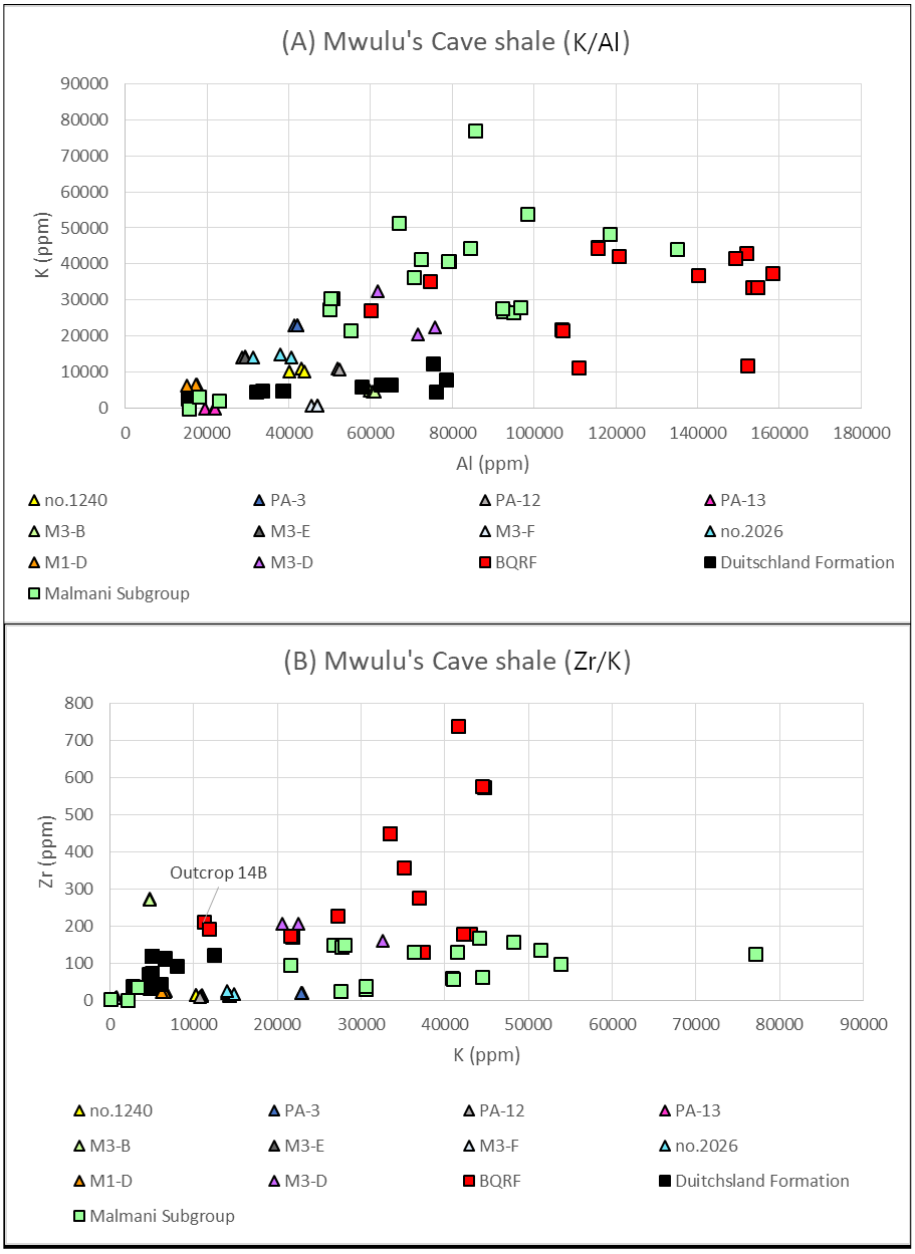

Figure 4.24: A) K/Al scatterplot of shale samples at Mwulu's cave. B) Zr/K scatterplot of shale samples at Mwulu's Cave.

Quartz

The most informative graphs for comparing Mwulu's Cave quartz samples are scatterplots Ti/Fe (Figure 4.25 A) and Si/Al (Figure 4.25 B). The Ti/Fe ratios of the quartz outcrop samples collected from the BRQF are diverse. These samples also have diverse Al contents and they have Si contents below 40%.

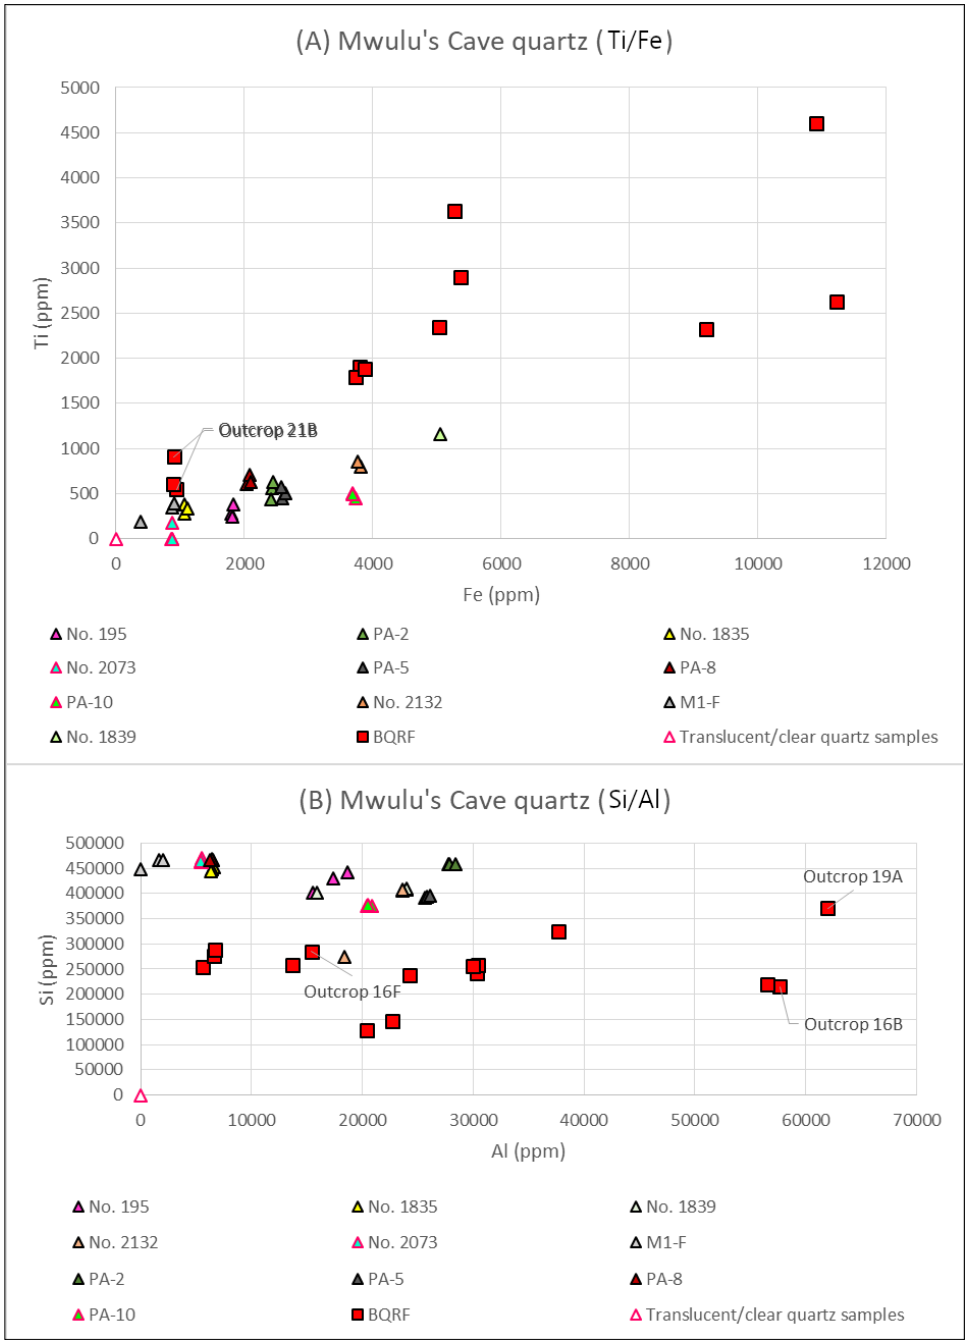

Figure 4.25: A) Ti/Fe scatterplot of quartz samples at Mwulu's Cave. B) Si/Al scatterplot of qaurzt samples at Mwulu's Cave.

Chert

Scatterplots Ti/Fe (Figure 4.26 A) and Si/Al (Figure 4.26 B) provide the most useful information for discriminating between chert samples collected from the BRQF and those collected from the Malmani Subgroup. The chert outcrop samples collected from the BRQF show diverse Ti/Fe and Si/Al ratios. The Fe content of the samples collected from the Malmani Subgroup is below 3000 ppm and the Ti content is below 800 ppm. They have an Al content below 2.1% and their Si content is between 33.9% and 41.3%.

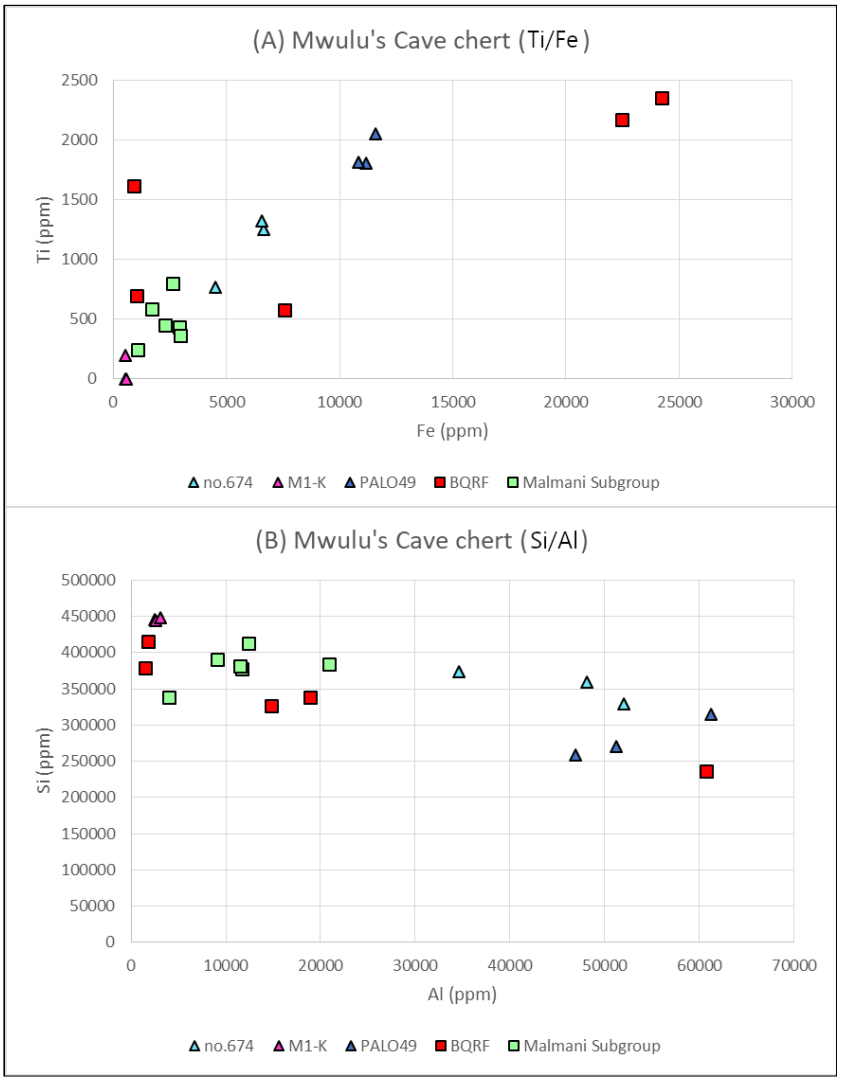

Figure 4.26: A) Ti/Fe scatterplot of chert samples at Mwulu's Cave. B) Si/Al scatterplot of chert samples at Mwulu's Cave.

Principal Component Analysis of Mwulu's Cave Samples

A total of 38 outcrop samples and 81 lithics from Mwulu's Cave were analysed through pXRF in this project. The results of this analysis were used to differentiate between the different rock types found around the site, and to to see how lithics grouped with the rock types and different foramtions within these rock types. The following elements were used in different PCA plots for this purpose: Al, Si, S, K, Ti, V, Cr, Mn, Cu, Zn, Fe, Ni, Rb, Sr, Y, Zr, Nb, Pb, Mo, and Th. As mentioned, only the first two principle components are plotted. The PCA results are given below and tables of the element coordinates for PC1 and PC2 can be found in Appendix B.

Differentiation of Rock Types

In the 'MW Rock Types' PCA plot (Figure 4.27), PC1 and PC2 show 53.7% of the total variation obtained through using elements Al, Si, P, S, K, Ti, Cr, Mn, Fe, Rb, Sr, Zr, and Nb. The best projected elements on PC1 (41.6% variation) are Rb, Nb, and K. The best projected elements on PC2 (12.1% variation) are Mn, S, and Fe.

As with the OBP rock types, two distinct groups are noted from the PCA plot (Figure 4.27). One with shale, and the other with quartzite, quartz, and chert. Although the shale samples show greater diversity in the elements best projected by PC1 and PC2, quartzite quartz, and chert have less Rb, Nb, and K. Many samples in these rock types are also poorer in Mn and Fe and richer in S in comparison to the shale samples. Shale can be clearly distinguished from the rest of the Mwulu's Cave rock types. It has minimal overlap with quartzite on the 80% significance level ellipse (fill) and partial overlap on the 95% significance ellipse (dash). All the rock types, with the exception of shale, overlap their 80% significance level ellipses.These rock types cannot be well differentiated from one another based on this plot.

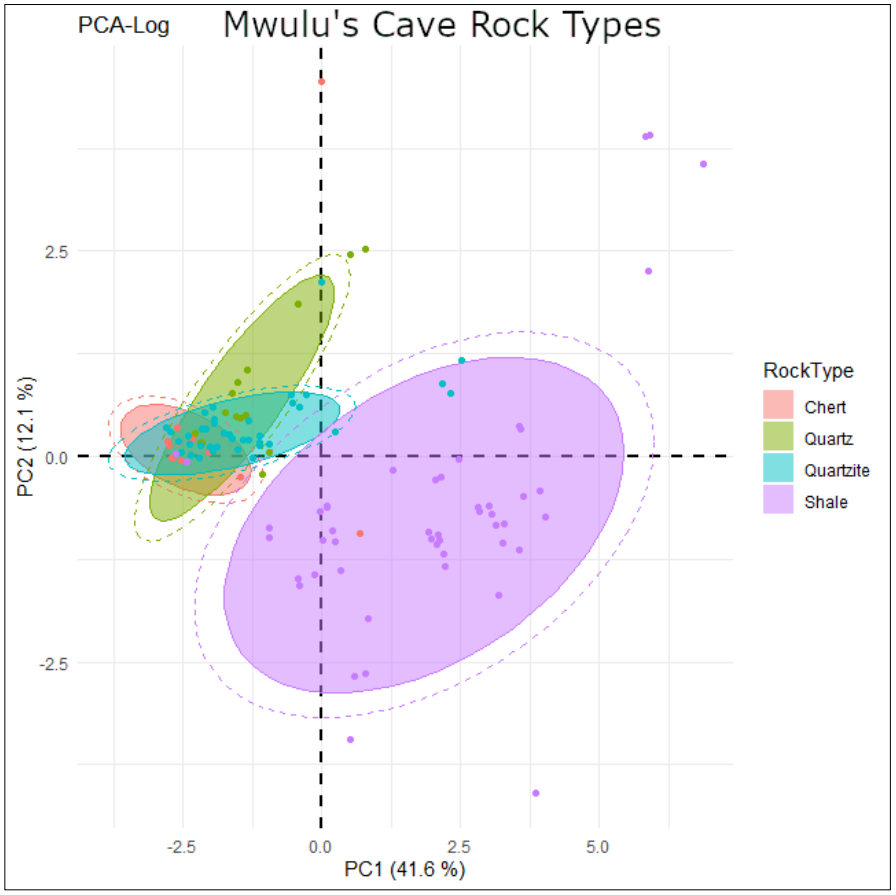

Figure 4.27: The PCA of Mwulu's Cave rock types from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash). Shale is well distinguished from the rest of the rock types.

PCA plot of Mwulu's Cave quartzite samples

The 'All quartzite samples' (outcrops and archaeological samples) PC1 and PC2 axes account for 67.5% of the total variation obtained by using elements Al, Si, P, Ti, Fe, Rb, Sr, and Zr (Figure 4.28). The best projected elements for the quartzite samples on PC1 (50.9% variation) are Fe, Sr, and Rb. and those on PC2 (16.6% variation) are P, Si, and Rb.

The BRQF and Malmani Fm geological samples cannot be confidently differentiated from each other using this plot because not enough Malmani Fm outcrop samples could be collected. Most quartzite lithics, however, lie within the BRQF 80% significance level ellipse or close to it. The rest of the lithics have more P, and less Si and Rb than

the samples from the BRQF and the lithics associated with it. The provenance of these lithics cannot be determined based on this plot.

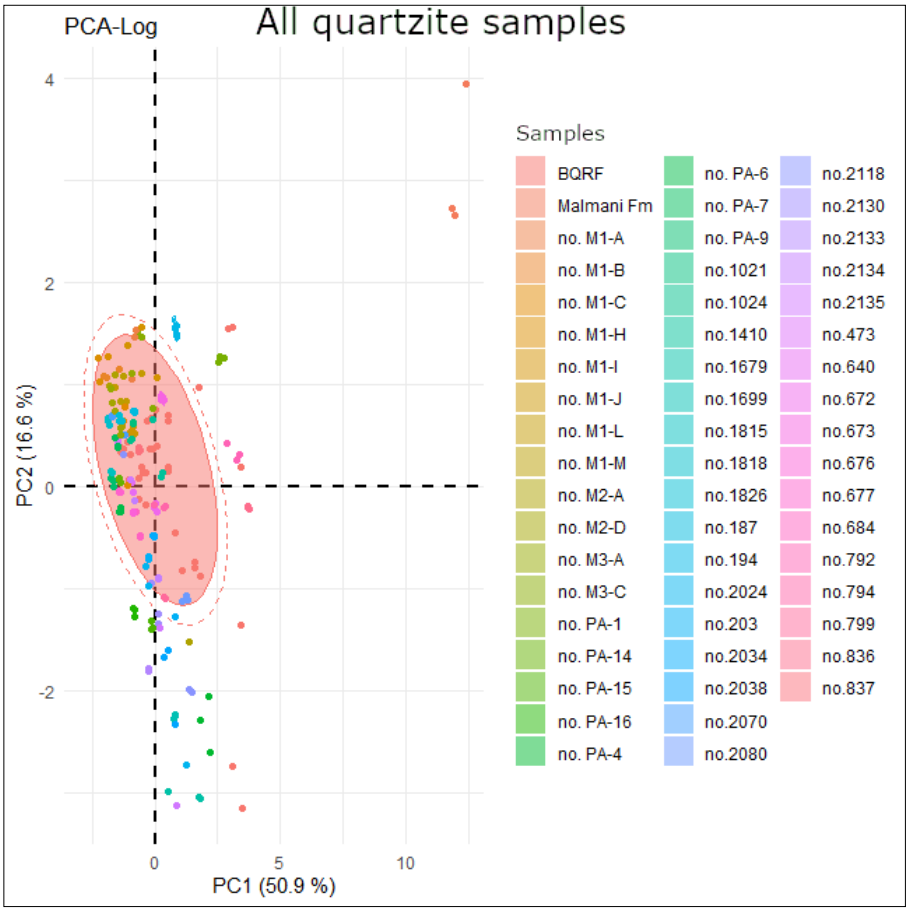

Figure 4.28: The PCA of Mwulu's Cave quartzite samples from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash). Most lithics plot within or close to the BRQF ellipse.

PCA plot of Mwulu's Cave shale samples

The 'Shale Formations' PCA plot shows that PC1 and PC2 account for 51.5% of the total variation obtained by using elements Al, Si, P, S, K, Ti, V, Cr, Mn, Fe, Cu, As, Rb, Sr, Y, Zr, Nb, and Th (Figure 4.29). The best projected elements for the shale formations on PC1 (35.6% variation) are Nb, Zr, and Ti and those on PC2 (15.9% variation) are As, Fe, and Th.

The BRQF, Duitschland Fm and Malmani Fm geological samples 80% significance level ellipses are all overlapping and most of the BRQF samples are noted in the Malmani Fm ellipse. Therefore these formations cannot be differentiated from each other using this plot. The Duitschland Fm is more diverse and richer in elements best projected by PC2 (As, Fe, and Th) compared to the other two formations. This plot canot tell us anything about the provenance of shale lithics because the formations overlap.

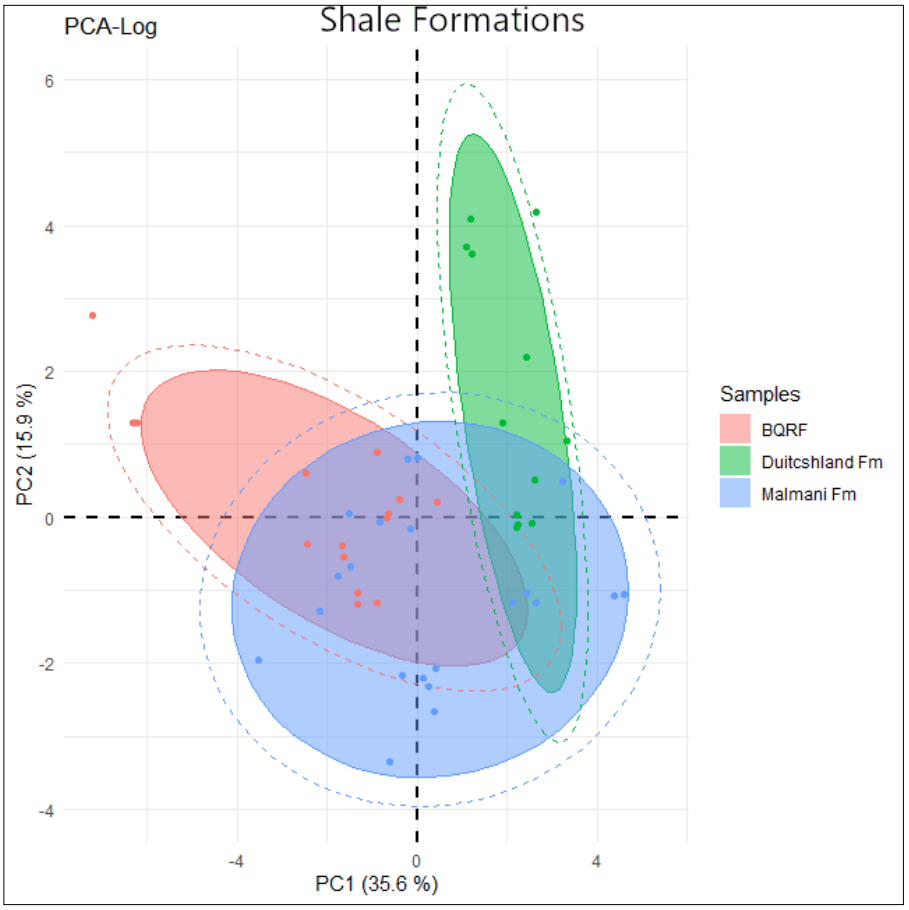

Figure 4.29: The PCA of overlapping Mwulu's Cave shale formations from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash).

PCA plot of Mwulu's Cave quartz samples

Only quartz raw materials from the BRQF were analysed. In the 'All quartz samples' (outcrops and archaeological samples) PCA plot (Figure 4.30), PC1 and PC2 show

71.1% of the total variation obtained through using elements Al, Si, P, Ti, and Fe. The best projected elements on PC1 (51.5% variation) are Fe, Al, and Si. The best projected elements on PC2 (19.6% variation) are P, Ti, and Al.

All of the quartz lithics lie within the the 80% significance level ellipse of the BRQF.

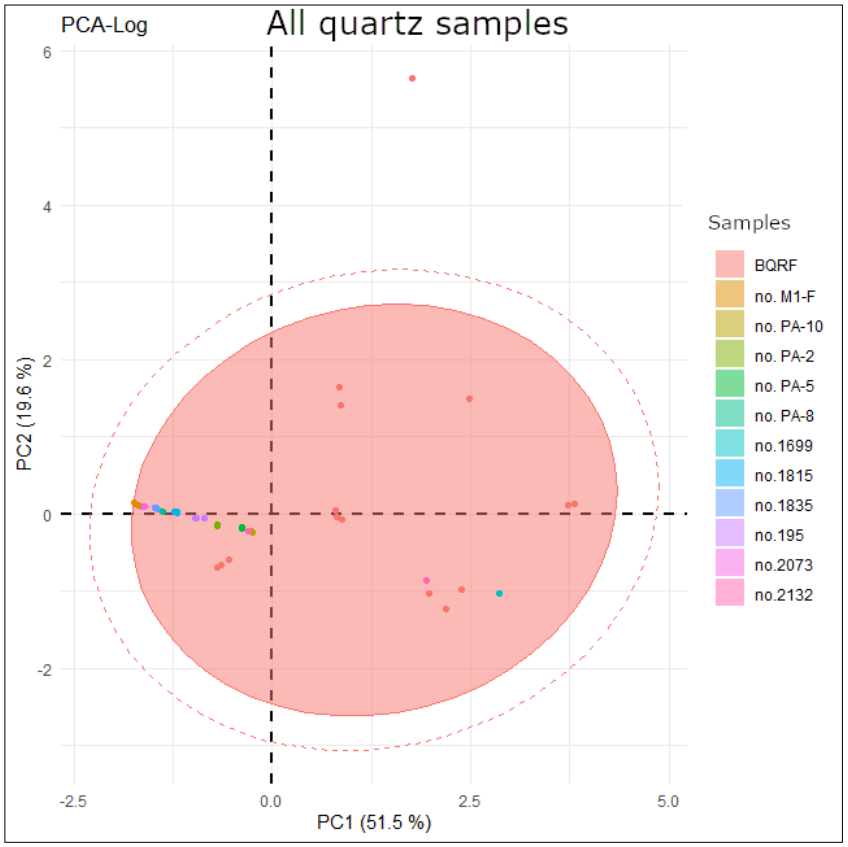

Figure 4.30: The PCA of Mwulu's Cave quartz samples from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash). All lithics plot within the BRQF ellipse.

PCA plots of Mwulu's Cave chert samples

The 'Chert Formations' PCA plot (Figure 4.31) shows that PC1 and PC2 account for 77.9% of the total variation obtained through using elements Al, Si, P, S, K, Ti, Cr, Mn, Fe, Rb, Sr, Zr, Nb, and Mo. The best projected elements on PC1 (50.7% variation) are Si, Zr, and Nb. The best projected elements on PC2 (27.2% variation) are P, S, and Sr.

The provenance of the chert lithics cannot be determined due to the overlap of the BRQF and Malmani Subgroup samples.

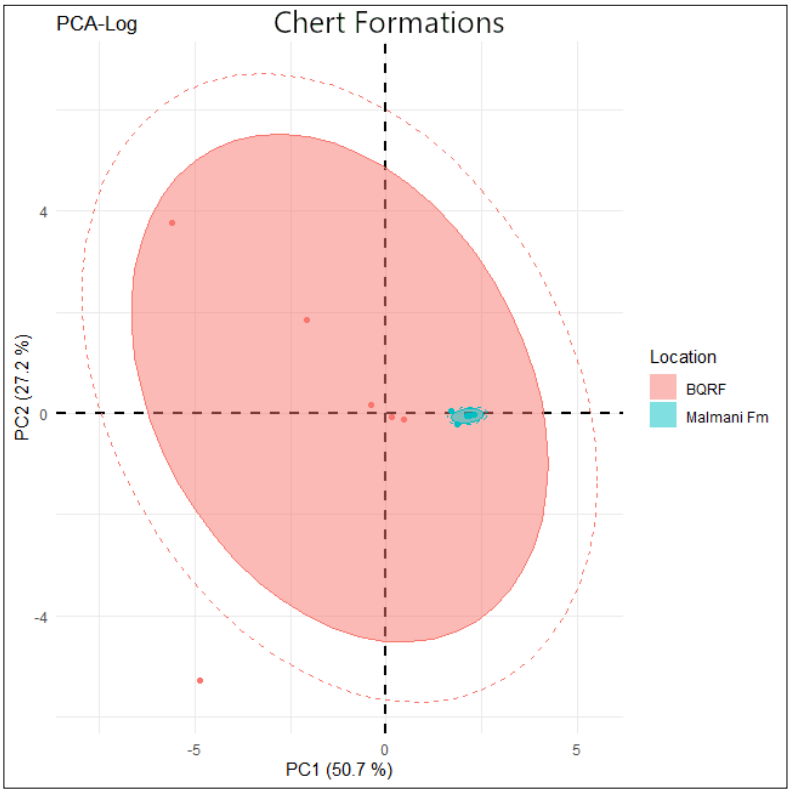

Figure 4.31: The PCA of overlapping Mwulu's Cave chert formations from pXRF data showing 80% significance level ellipses (fill) and 95% significance ellipses (dash).

4.3 Thin section descriptions

In the following sections, petrographic descriptions of samples associated with OBP and Mwulu's Cave are given. Discriminating characteristics between the quartzite samples are tabulated in Tables 4.1 and 4.2 showing their presence in each sample. Detailed petrographic descriptions of OBP and Mwulu's Cave's thin sections are found in APPENDIX C.

4.3.1 Olieboomspoort Rock shelter thin section descriptions

Quartzite (possibly quartz arenite)

No. 486 and No. 3478 (Figure 4.32) are the only two thin sectioned samples that represent quartzite lithics at OBP. They are predominantly composed of quartz grains (~ 90%) in a dark, microcrystalline matrix (<10%). Minor minerals (<5%) such as muscovite are noted in No. 486. The quartz grains in both samples are coarse and have shapes ranging from angular to sub-rounded. Their birefringence is low (grey) and the grains in No. 3478 show both uniform and undulose extinction. The quartz grains in No. 486 only have uniform extinction. The muscovite is colourless under PPL and its cleavage is evident. Under XPL it has high birefringence. Moderate to good sorting is noted in these quartzite samples and they are clast supported. Both samples have interlocking grains with no visible pore spaces. Syntaxial quartz cement in both samples occurs in 40-50% of the quartz grains. The grains in No. 3478 are pitted and fractured and those in No. 486 have deformation lamellae (30-40%). Quartz characteristics used to group quartzite samples are shown in Table 4.1.

Only CMF1 (Figure 4.32 C) has quartzite characteristics. It has around 90% quartz grains in a minimal matrix. They have a low birefringence and 20-30% of them show undulose extinction while the rest show uniform extinction. This quartzite is well-sorted and has interlocking quartz grains. 45% of the grains have quartz syntaxial cement outside of their original boundaries. The grains are pitted and about 25% of them have embayments. Black staining is noted throughout the sample and very little deformation lamellae are present. Quartz characteristics used to group quartzite samples are shown in Table 4.1.

Table 4.1: Quartz characteristics of quartzite samples at Olieboomspoort Rock Shelter.

OBP Quartz Characteristics						
Sample no.	**Undulose extinction**	**Deformation lamellae**	**Concave-convex boundary relationships**	**Syntaxial cement**	**Stylolites**	**Interloc-king quartz**
No. 486	25%	30-40%	85%	40%	-	90%
No. 3478	20%	-	70%	40-50%	-	>90%
CMF1	20-30%	<10%	75%	45%	-	>90%

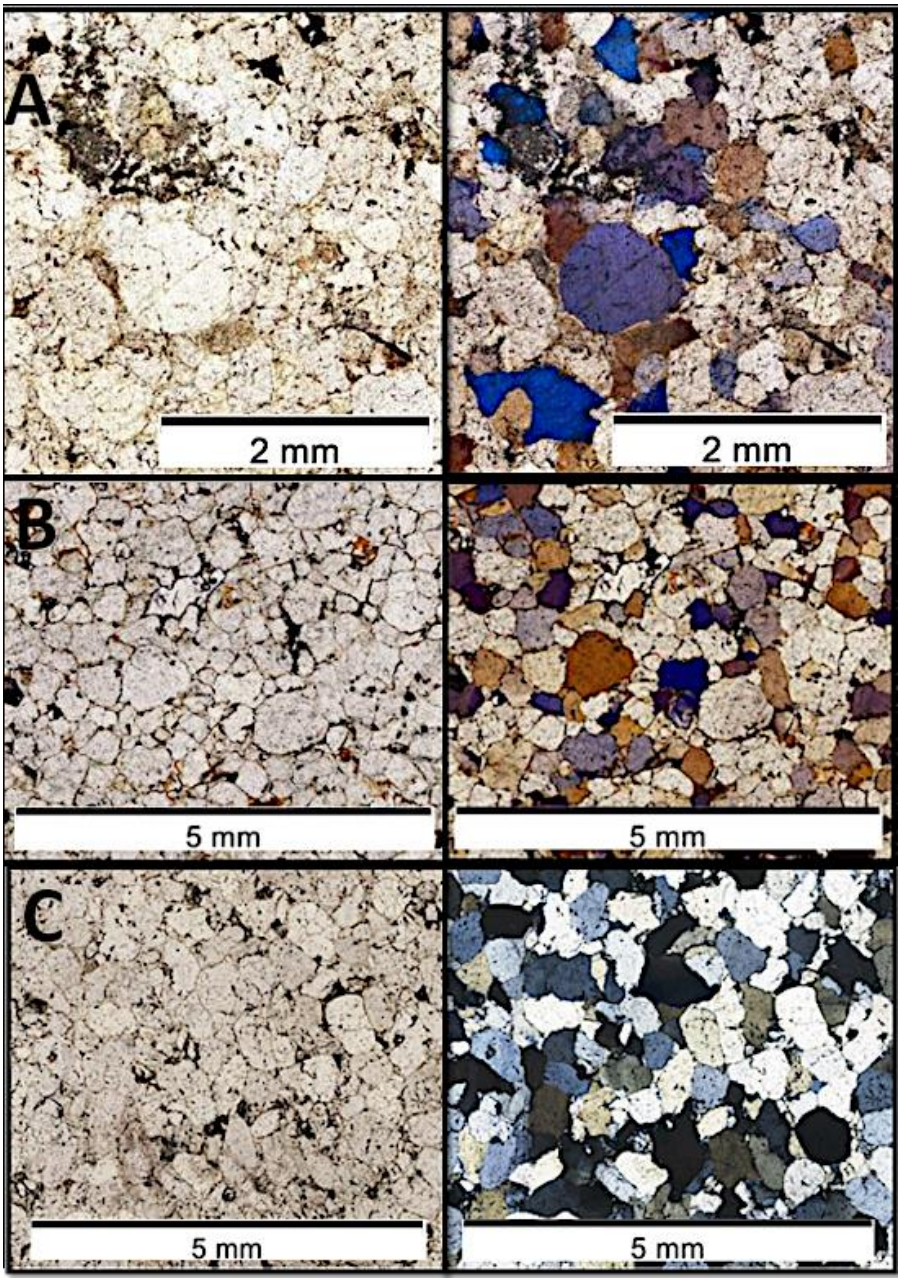

Figure 4.32: Light microscope image of A) No. 486 showing interlocking quartz grains, B) No. 3478 showing sub-rounded and interlocking quartz grains, and C) CMF1 showing its interlocking and annealing quartz grains in PPL (left) and XPL (right).

Sandstone

No. 1194 is a greywacke and No. 2402 is a sub-litharenite (Figure 4.33). Both samples have 60-80% quartz grains in a visible matrix (20% in 1194). Other minerals like muscovite and lithic fragments are noted in No. 2402, and opaque minerals are present

in No. 1194. No. 1194 has quartz phenoclasts. The quartz grains in this rock type are angular, sub-angular, and sub-rounded. They have low grey interference colours and show both undulose and uniform extinction. Both samples have recrystallized quartz grains (10-40%). The muscovite in No. 2402 has visible cleavages and bright interference colours under XPL. The lithic fragments are multi-coloured under XPL. These sandstones are poorly sorted. The quartz grains are pitted and fractured, and those in no. 2402 have deformation lamellae (20%).

Two sandstones are identified in the geology around OBP. These are arkose (OBP 7; Figure 4.33 C) and greywacke (OBP 8A; Figure 4.33 D). A similar amount of quartz is noted in both sandstones (55-60%). Alkali feldspar (40%) is a component of the arkose, whereas muscovite (20%) and opaque minerals (5%) in a significant matrix (20%) form part of the greywacke mineralogy. Both samples have a degree of irregularly shaped quartz grains amidst the sub-rounded, or angular to sub-angular grains. All of these have a low birefringence and uniform extinction although OBP 8A shows undulose extinction too (55%). 45% of the quartz grains in OBP 7 have been recrystallised. The alkali feldspar in OBP 7 is a cloudy brown under PPL and has a low birefringence. The muscovite in OBP 7 has a high birefringence and becomes extinct parallel to its perfect cleavage. Both samples are poorly sorted. In OBP 7, the alkali feldspar has a perthitic texture. Black and orange staining, is noted in association with the grains throughout the sample (OBP 7). The grains in OBP 7 are pitted (90%) and fractured (40-50%). In OBP 8A, 25% of the quartz grains have deformation lamellae.

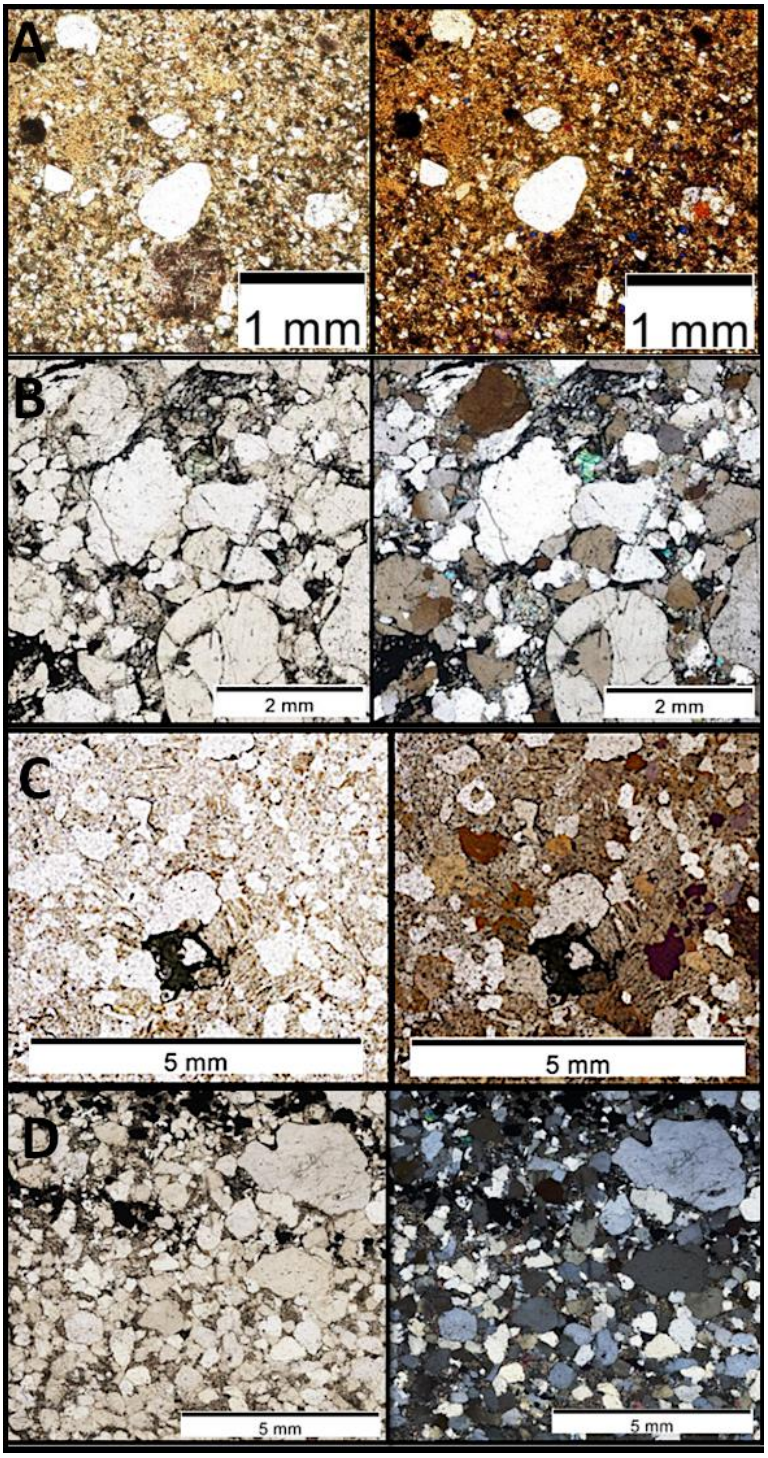

Figure 4.33: Light microscope image of A) No. 1194 showing its poor sorting and quartz phenoclasts, and B) No. 2402 showing the poorly sorted nature of the sandstone in PPL (left) and XPL (right). C) OBP 7 shows the relationship between quartz grains and alkali feldspar grains in PPL and D) is OBP 8A showing its porosity and sorting of grains in PPL (left) and XPL (right).

Shale

No. 164 and YRS1-D (Figure 4.34) are very fine-grained shale samples. The only minerals large enough to analyse in both these samples are opaque minerals (10-15%) and chlorite (20-25%). The chlorite has a low birefringence (brown anomalous interference colour) under XPL. Chlorite occurs in clusters in both samples. In No. 164, it surrounds the opaque minerals throughout the sample.

OBP 10A (Figure 4.34 C) is composed of 20% opaque minerals in a very fine-grained, green-brown matrix (80%). It has cloudy patches of opaque mineralisations in some parts of the sample.

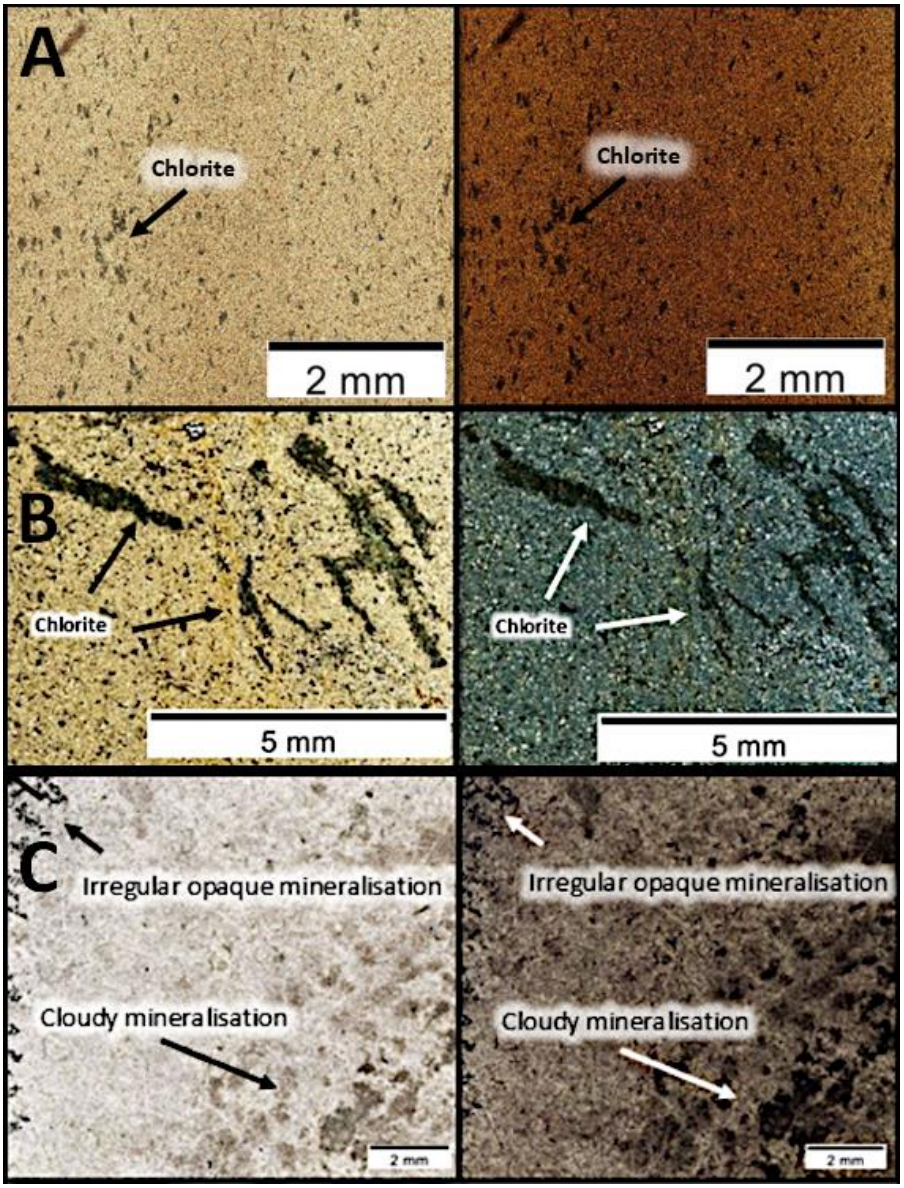

Figure 4.34: Light microscope image of A) No. 164, B) YRS1-D showing cryptocrystalline texture and chlorite, and C) OBP 10A showing its cryptocrystalline texture, and cloudy, opaque mineralisation in PPL (left) and XPL (right).

Dolerite

The only thin sectioned dolerite sample is No. 458 (Figure 4.35 A). It has white plagioclase laths (80%) in a black matrix. Other finer minerals like hornblende and augite are also noted in this sample through their bright blue, yellow, and green

interference colours under XPL. The plagioclase laths have a low birefringence and are randomly oriented throughout the sample.

OBP 4G (Figure 4.35 B) has mineralogy consisting of plagioclase laths (80%), white euhedral phenocrysts (5%), and brown biotite (15%). The plagioclase laths and phenocrysts have a low birefringence whereas the biotite shows third-order orange-yellow interference colours under XPL. These minerals are randomly orientated throughout the sample. The phenocrysts are altered and have brown mineralisation along their grain boundaries.

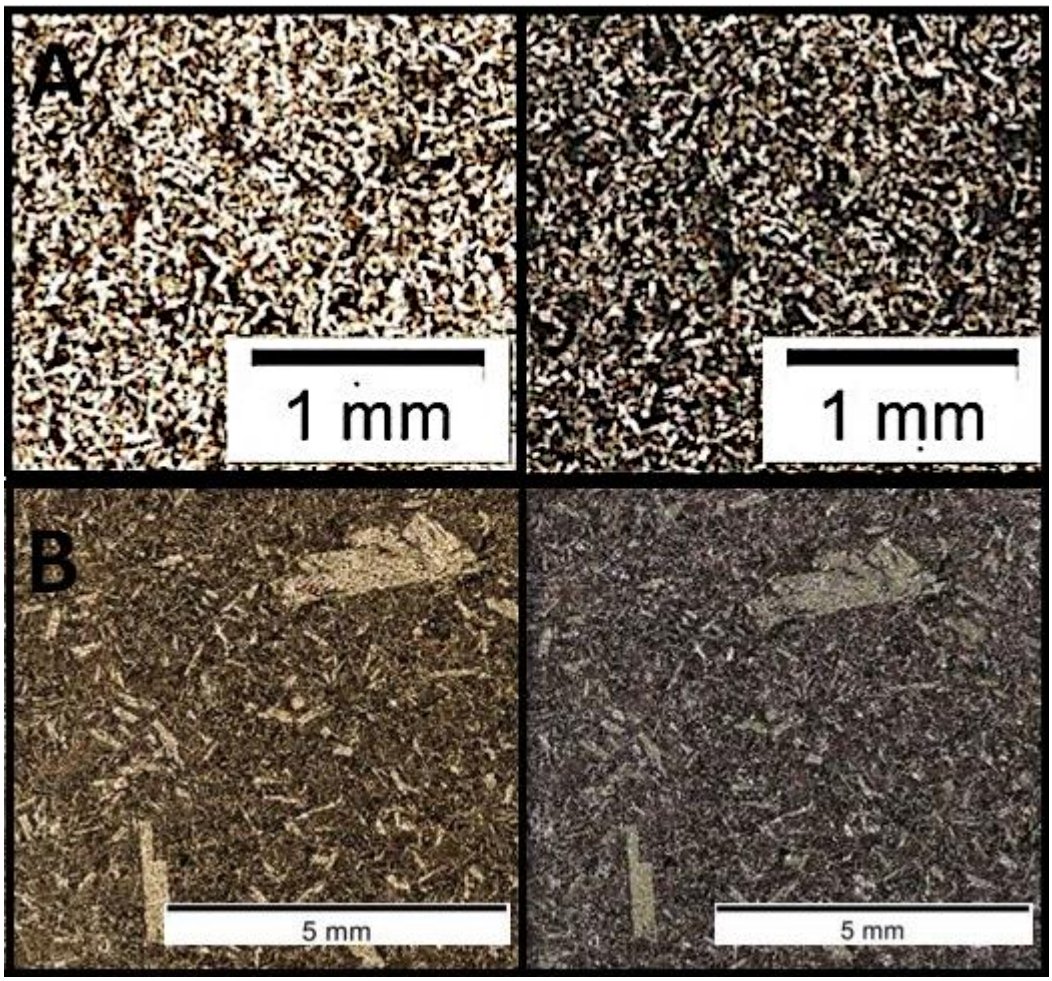

Figure 4.35: Light microscope image of A) No. 458 and B) OBP 4G showing randomly oriented plagioclase laths in PPL (left) and PXPL (right).

4.3.2 Mwulu's Cave thin section descriptions

Quartzite (possibly quartz arenite)

No. 640 (Figure 4.36 A); No. 1021 (Figure 4.36 B); and M1-J (Figure 4.36 C) are quartzites with 90% or more quartz grains in their mineralogy. The dark matrix in No. 640 and M1-J (~10%) is dark and multi-coloured under XPL. Quartz grains from all three samples have first-order grey and white interference colours. They also have undulose extinction (45-80%) and uniform extinction. Sorting varies across these quartzite samples from poor to well-sorted. No. 640 and M1-J have interlocking quartz grains whereas the grains in No. 1021 are annealing. Only No. 640 and M1-J have grains with quartz syntaxial cement. Pitting is evident in quartz grains in all three samples and no deformation lamellae are noted. Quartz characteristics used to group quartzite samples are shown in Table 4.2.

Outcrop 16A (Figure 4.36 D) and G2A (Figure 4.36 E) are quartzite samples composed of quartz grains (90%) in a dark, microcrystalline matrix (10%). G2B (Figure 4.36 F), on the other hand, has coarse quartz grains (65%) as well as finer quartz grains (35%) in its mineralogy. These quartzite samples have quartz grains of varying shapes ranging from angular to sub-rounded. The quartz grains have low grey interference colours and a significant amount of them undergo undulose extinction (70-75%). The microcrystalline matrix is dark and multi-coloured under XPL. G2A and G2B are poorly sorted unlike the moderately to well-sorted Locality 16A. However, Locality 16A and G2B have more interlocking quartz grains in comparison to G2A. In fact, G2B has a high degree of annealing between the grains. Locality 16A and G2B have quartz syntaxial cement outside of 15-40% of their quartz grains. Pitting is noted in the quartz grains of all three samples and embayments in the grains are only seen in G2A (5%). Deformation lamellae are scarce across all of the quartzite samples. Quartz characteristics used to group quartzite samples are shown in Table 4.2.

Table 4.2: Quartz characteristics of quartzite samples at Mwulu's Cave

Mwulu's Cave Quartz Characteristics

Figure 4.36: Light microscope images of A) No. 640 showing interlocking quartz grains, and undulose extinction in PPL (left) and XPL (right). B) No. 1021 shows the porous nature of the rock and its coarse quartz grains, while C) M1-J shows its poorly sorted quartz grains in PPL (left) and XPL (right). D) Outcrop 16A shows interlocking and annealed quartz grains (PPL; left), and undulose extinction (XPL; right). E) Outcrop G2A shows poorly sorted quartz grains. Some of the grains show undulose extinction in XPL (right). F) G2B shows interlocking and annealed quartz grains in PPL (left) and XPL (right). Undulose extinction is also noted under XPL.

Sandstone

M3-B (Figure 4.37) is made of detrital quartz grains (60%); biotite (30%); and sedimentary lithic fragments in a dark matrix (10%). The quartz grains are round to sub-rounded and have first-order white and grey interference colours. Most of them undergo uniform extinction while about 10% of them undergo undulose extinction. Some of the biotite minerals are euhedral and show cleavage. They have a bright yellow interference colour and go extinct parallel to their cleavage. This sandstone is well-sorted although 20% of the rock is of pore spaces. The biotite and matrix fill the spaces between the quartz grains.

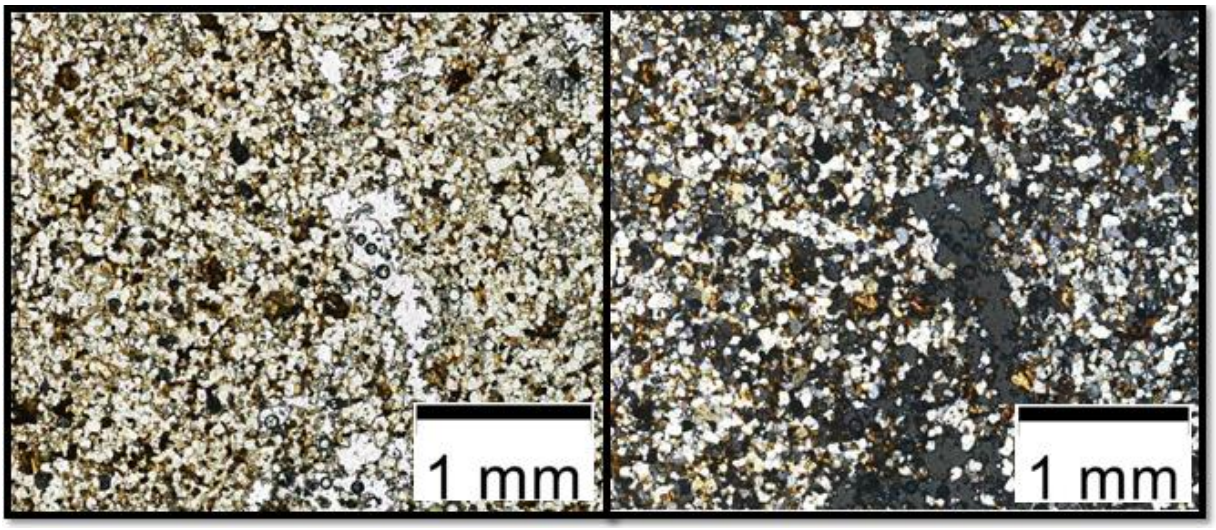

Figure 4.37: Light microscope images of M3-B showing its fine-grained texture and pore spaces in PPL (left) and XPL (right).

Shale

M3-E (Figure 4.38 A) is a green-brown shale with about 20% opaque minerals in its matrix. This matrix is very fine-grained and is dark and multi-coloured under XPL. Within this matrix, pore spaces are noted. These occupy about 10% of the rock.

The shale at Outcrop 4A (Figure 4.38 B) has opaque minerals (5%) that have white rims in a very fine-grained matrix. A single orange mineral (isotropic in XPL) is noted in the thin section. This shale has a foliation running across it. White and grey grains are evident within this foliation.

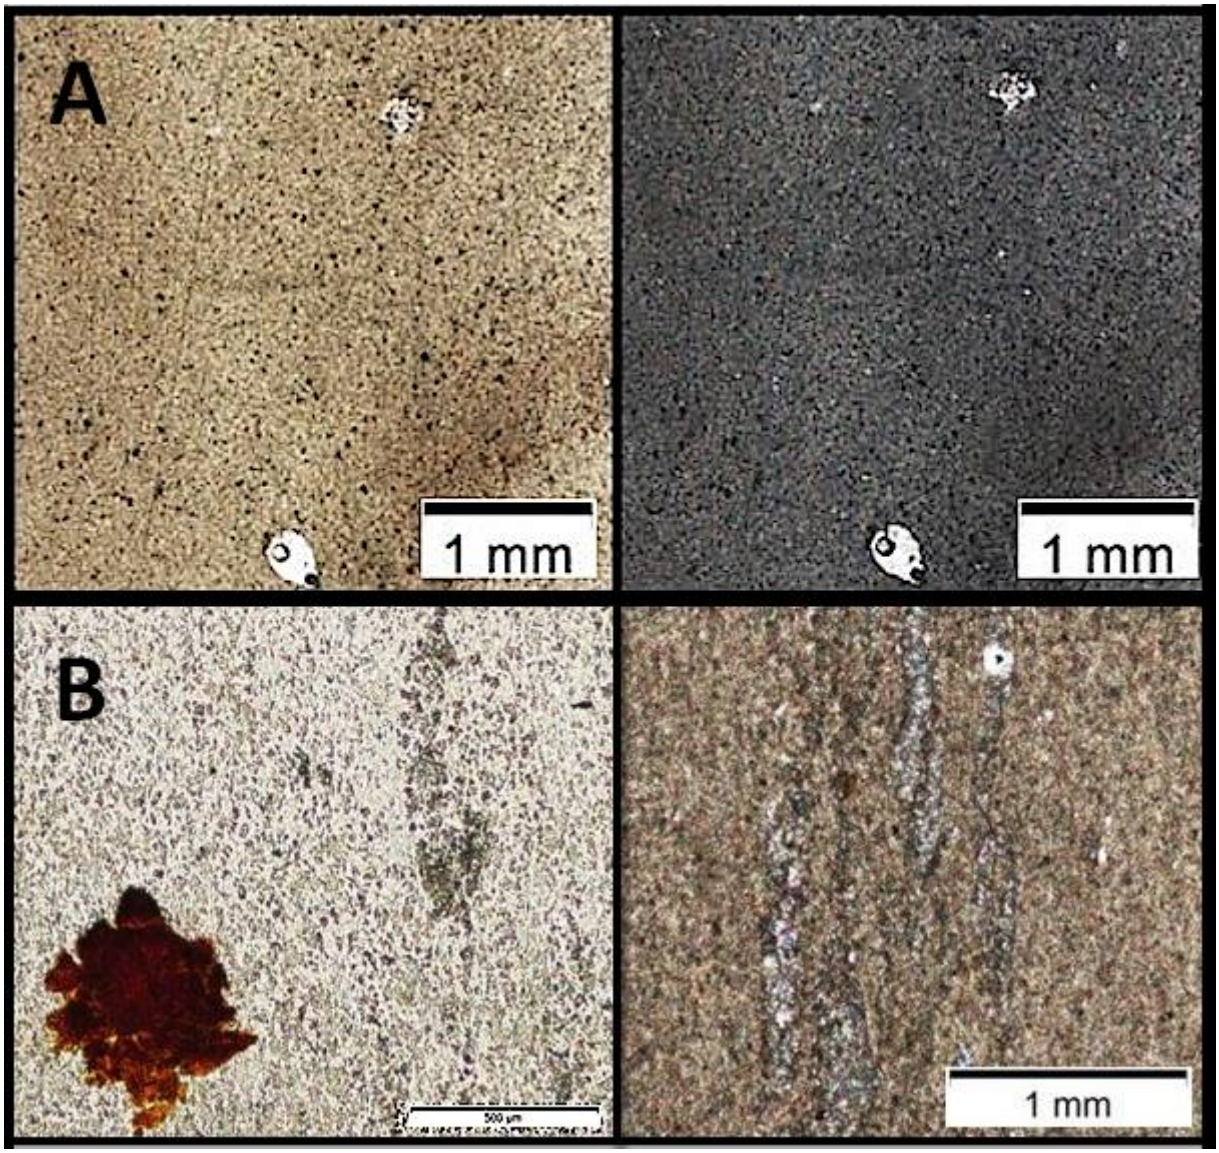

Figure 4.38: Light microscope images of A) M3-E showing its cryptocrystalline texture in PPL (left) and XPL (right). B) Outcrop 4A shows its cryptocrystalline texture and orange mineral in PPL (left) and foliated minerals in XPL (right).

4.4 Inductive Coupled Plasma Mass Spectrometry Results

Only a few lithic samples were analysed using ICP-MS due to its destructive nature. Quartzite, shale, sandstone, and dolerite samples from OBP and the geology around it were analysed (Table 3.5). Quartzite, shale, and chert samples from Mwulu's Cave and the geology around it were analysed (Table 3.5). Due to the small number of samples

being analysed, the point of this analysis is to refine some of the results obtained through pXRF. Full ICP-MS data and standards can be found in APPENDIX D.

4.4.1 Olieboomspoort Rock Shelter Inductive Coupled Plasma Mass Spectrometry data

Quartzite

The most informative scatterplots to compare quartzite lithics from OBP and a quartzite outcrop sample from the Cleremont Formation are Zn/Cu (Figure 4.39 A), Zr/La (Figure 4.39 B), Sr/Rb (Figure 4. 39 C), and Ba/Ti (Figure 4. 39 D). The Cleremont Formation quartzite sample has a Cu content of 2.1 ppm, and a Zn content of 4.5 ppm. The La content of this sample is 6.5 and its Zr content is 31.3 ppm. It has an Rb content of 10.0 ppm and a Sr content of 3.678 ppm. Lastly, its Ti content is 191.6 ppm and its Ba content is 124.2 ppm.

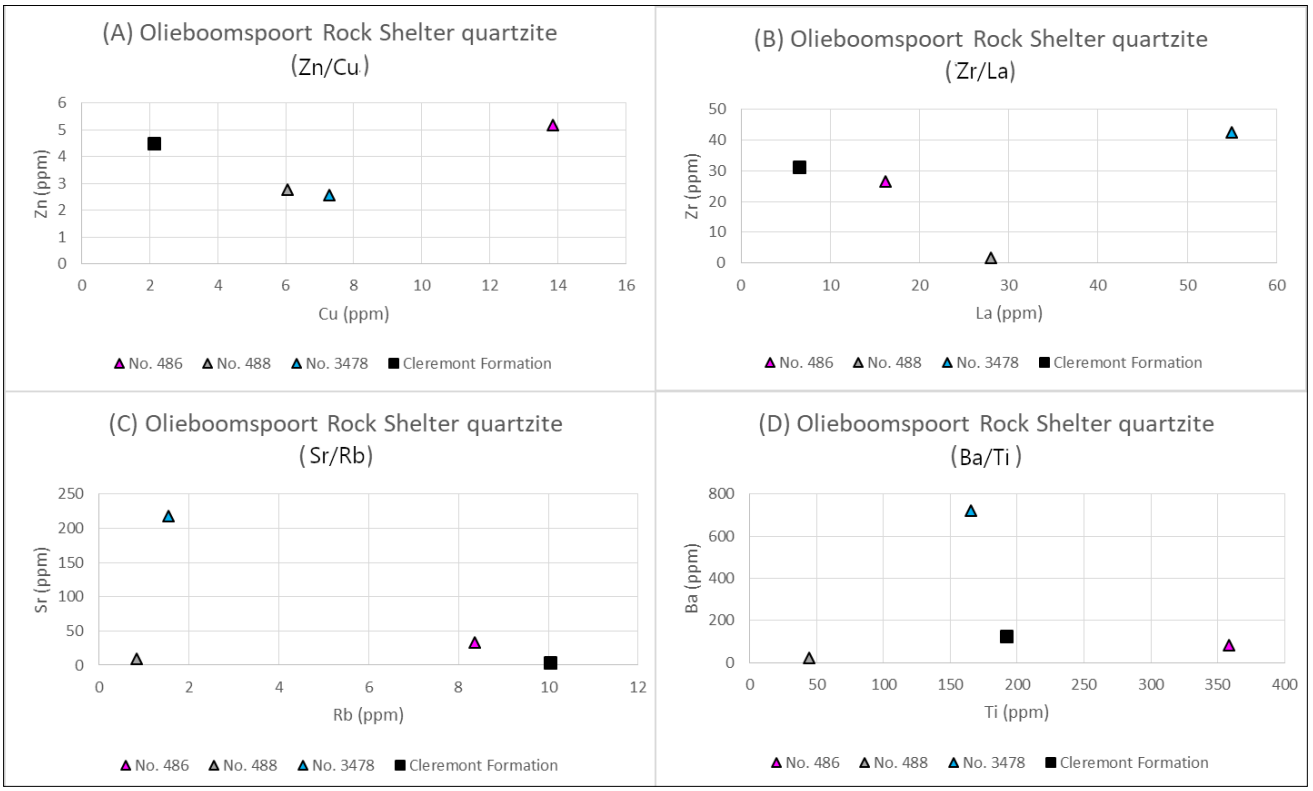

Figure 4.39: A) Zn/Cu, B) Zr/La, C) Sr/Rb, and D) Ba/Ti scatterplots of quartzite samples from OBP.

Shale

The Zr/La (Figure 4. 40 A) and Ni/Cr scatterplots (Figure 4. 40 B) offer the most useful information for comparing shale lithics from OBP with the geological sample collected around the Mogalakwena Formation. The geological sample has a La content of 1.7 ppm and a Zr content of 1.1 ppm. Its Cr content is 4.1 ppm and its Ni content is 6.0 ppm.

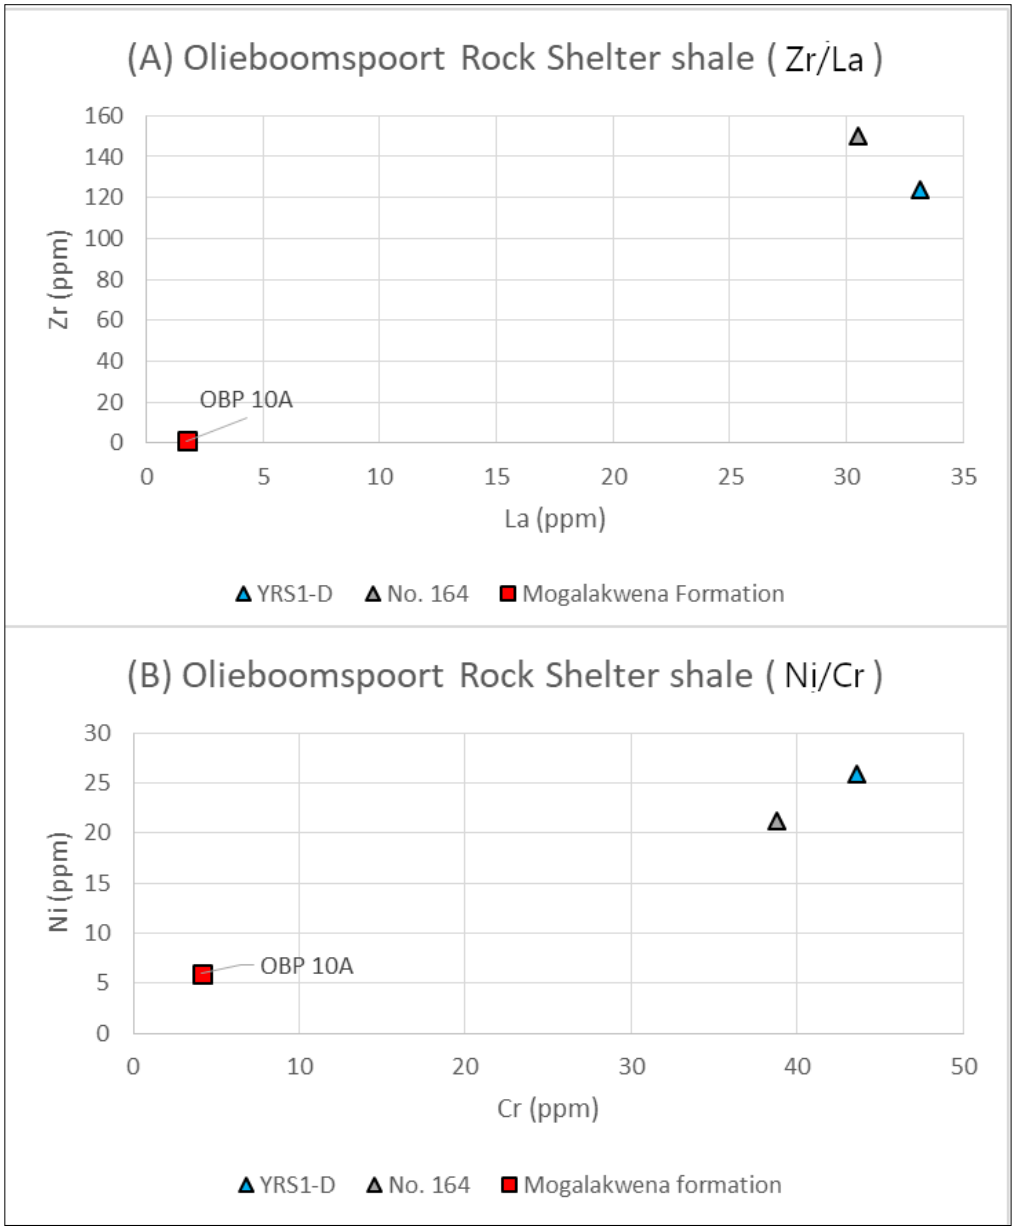

Figure 4.40: A) Zr/La scatterplot of shale samples at OBP. B) Ni/Cr scatterplot of shale samples at OBP.

Sandstone

Four scatterplots are useful in comparing OBP lithics to geological samples collected near the Mogalakwena Formation. The Zn/Cu scatterplot (Figure 4.41 A) shows that the geological samples have a Cu and Zn content between 2.9 ppm and 7.3 ppm, and 16.7 ppm and 20.1 ppm, respectively. They have a La and Zr (Figure 4.41 B) content between 44.3 ppm and 83.9 ppm, and 122.8 ppm and 175.5 ppm, respectively. The samples have a Th content between 26.3 ppm and 36.5 ppm, and an Sc content between 0.3 ppm and 4.3 ppm (Figure 4. 41 C). The Ti content of these samples is between 487.2 ppm and 1477.8 ppm, and their Ba content is between 114.1 ppm and 210.0 ppm (Figure 4. 41 D).

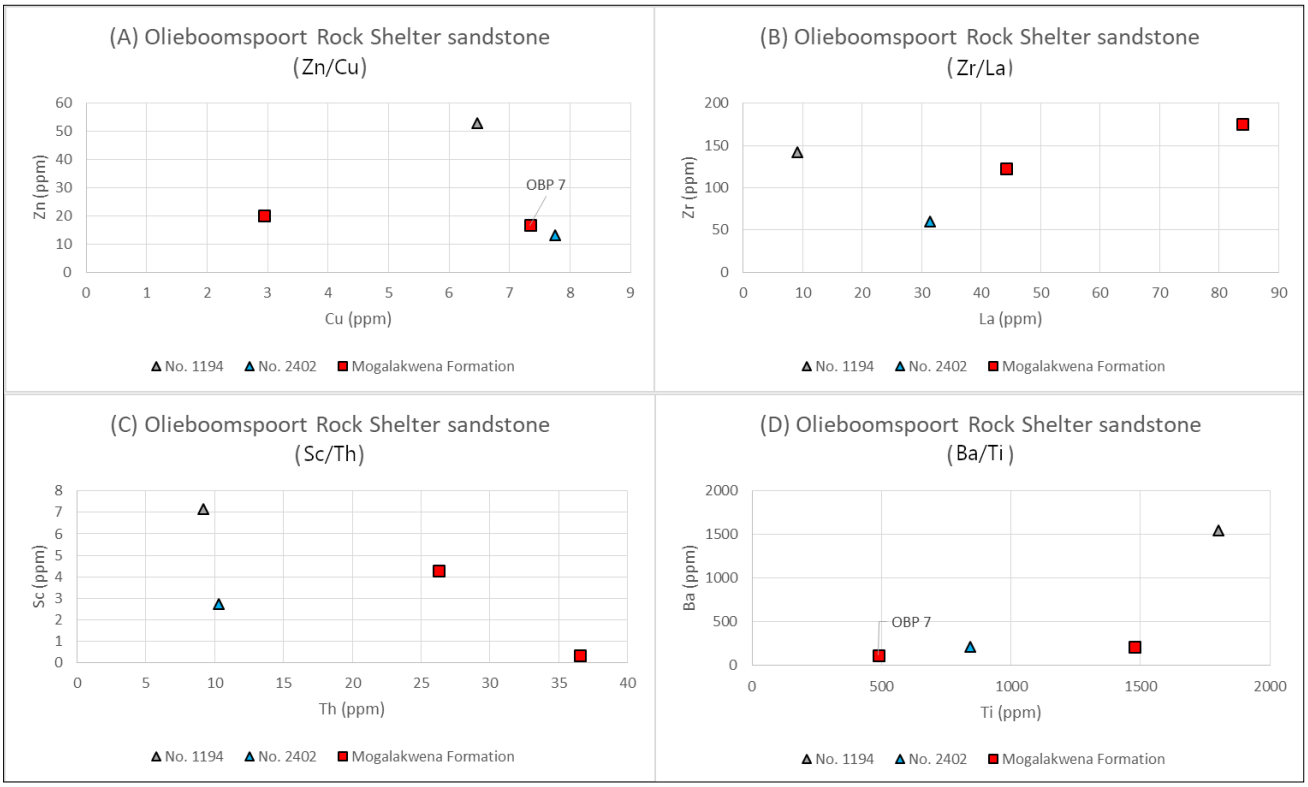

Figure 4.41: A) Zn/Cu, B) Zr/La, C) Th/Sc, and D) Ba/Ti scatterplots of sandstone scatterplots at OBP.

Dolerite

The Mogalakwena Formation dolerite geological sample (OBP 4G) has a Cr content of 14.6 ppm and a Ni content of 103.4 ppm on the Ni/Cr scatterplot (Figure 4.42).

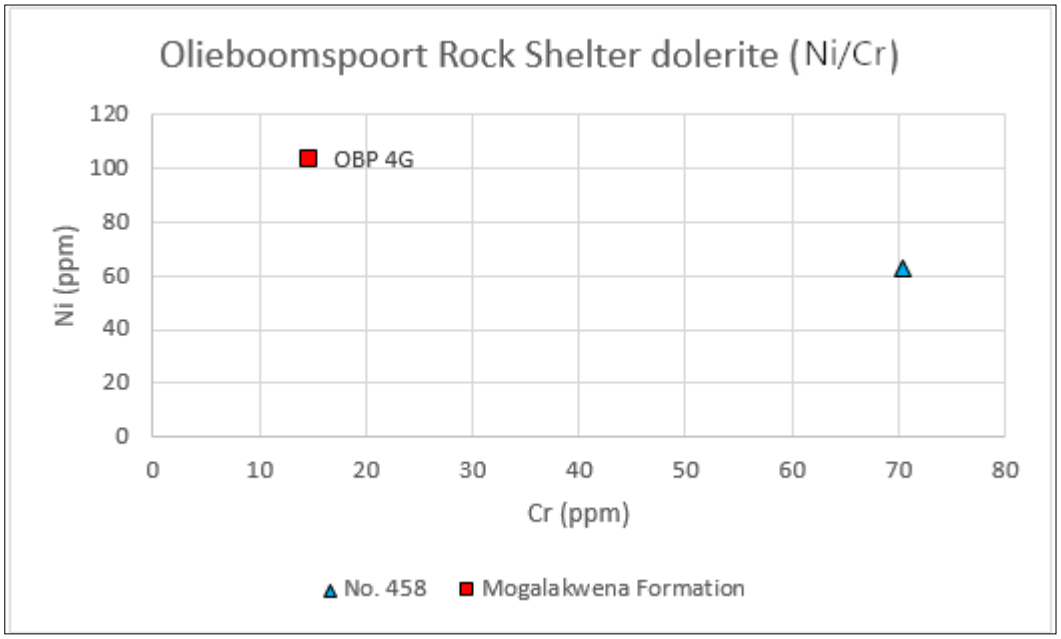

Figure 4.42: Ni/Cr scatterplot of dolerite samples at OBP.

4.4.2 Mwulu's Cave Inductive Coupled Plasma Mass Spectrometry data

Quartzite

The most informative scatterplots for comparing quartzite lithics from Mwulu's Cave with outcrop samples from the BRQF are Zn/Cu (Figure 4. 43 A), Zr/La (Figure 4.43 B), Sr/Rb (Figure 4.43 C), and Ba/Ti (Figure 4.43 D). The outcrop samples have a Cu content between 2.3 ppm and 12.5 ppm, and a Zn content between 3.2 ppm and 5.2 ppm. The rest of the scatterplots show that the BRQF quartzite samples have diverse ratios.

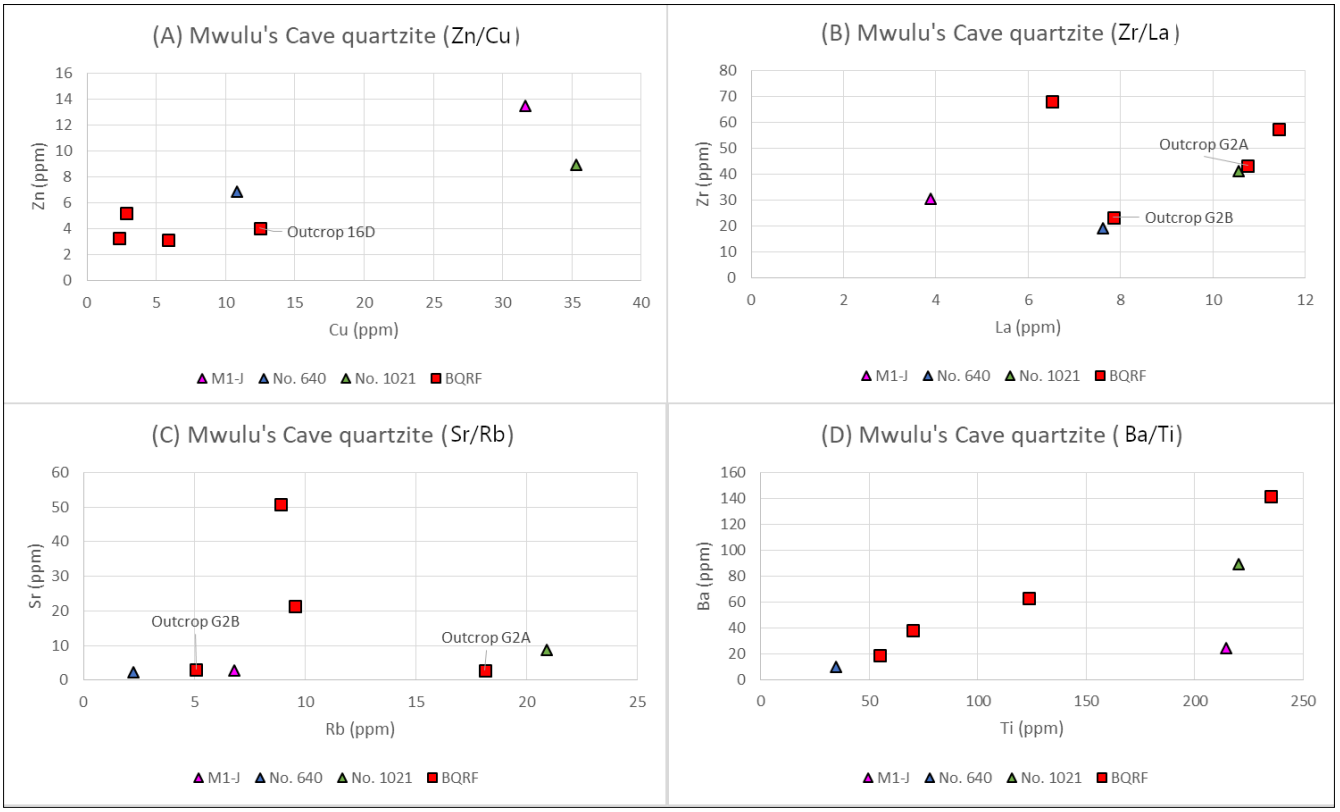

Figure 4.43: A) Zn/Cu, B) Zr/La, C) Sr/Rb, and D) Ba/Ti scatterplots of quartzite samples at Mwulu's Cave.

Shale

Scatterplots Zr/La (Figure 4.44 A) and Ni/Cr (Figure 4.44 B) are the most useful in comparing Outcrop 4A of the Malmani Subgroup and the shale lithics from Mwulu's Cave. The outcrop sample has a La content of 4.2 ppm and a Zr content of 61.9 ppm. It also has a Cr content of 543.7 ppm and a Ni content of 52.873 ppm.

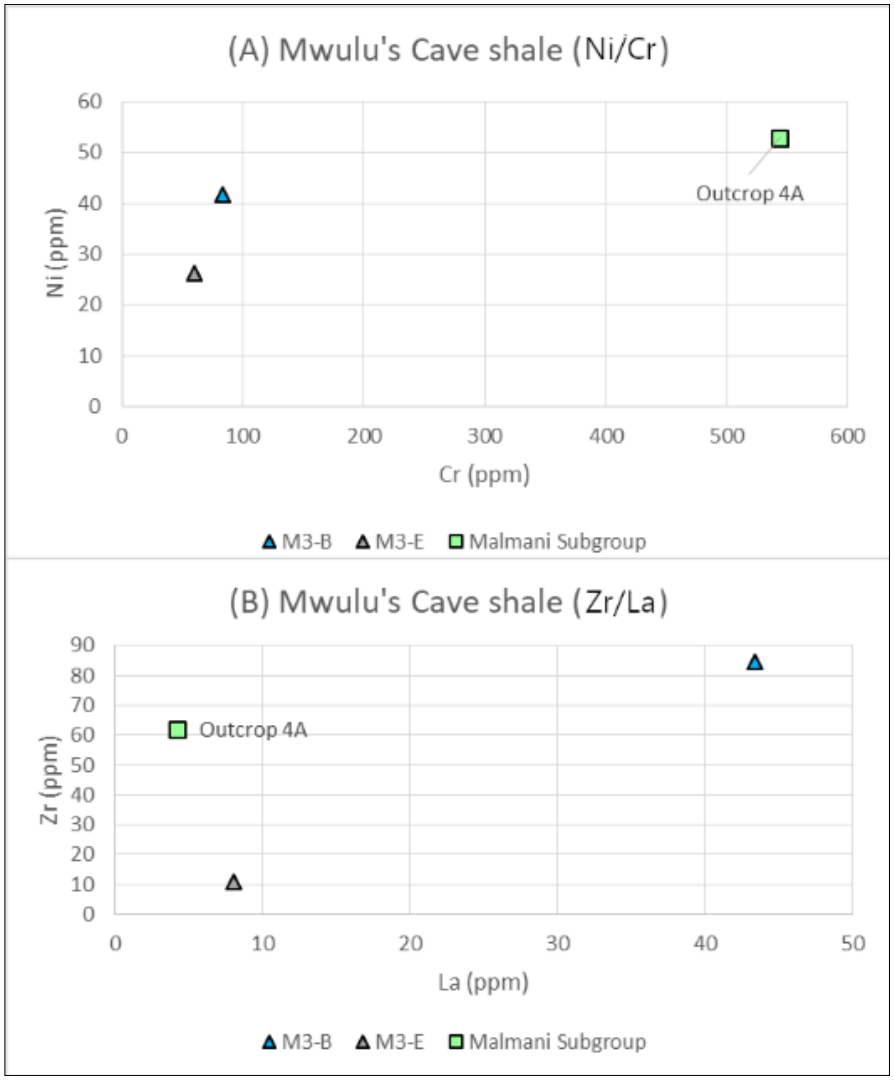

Figure 4.44: A) Zr/La and B) Ni/Cr scatterplots of shale samples at Mwulu's Cave.

Chert

The Zn/Cu (Figure 4. 45 A), U/La (Figure 4.45B), and Ti/P (Figure 4.45 C) scatterplots are the most useful to compare Mwulu's Cave chert lithics and the chert outcrop sample collected from the BRQF. The chert outcrop sample has a Cu content of 10.5 ppm, a Zn content of 3.9 ppm, a La content of 4.3 ppm, a U content of 0.9 ppm, a P content of 533.2 ppm, and a Ti content of 97.8 ppm.

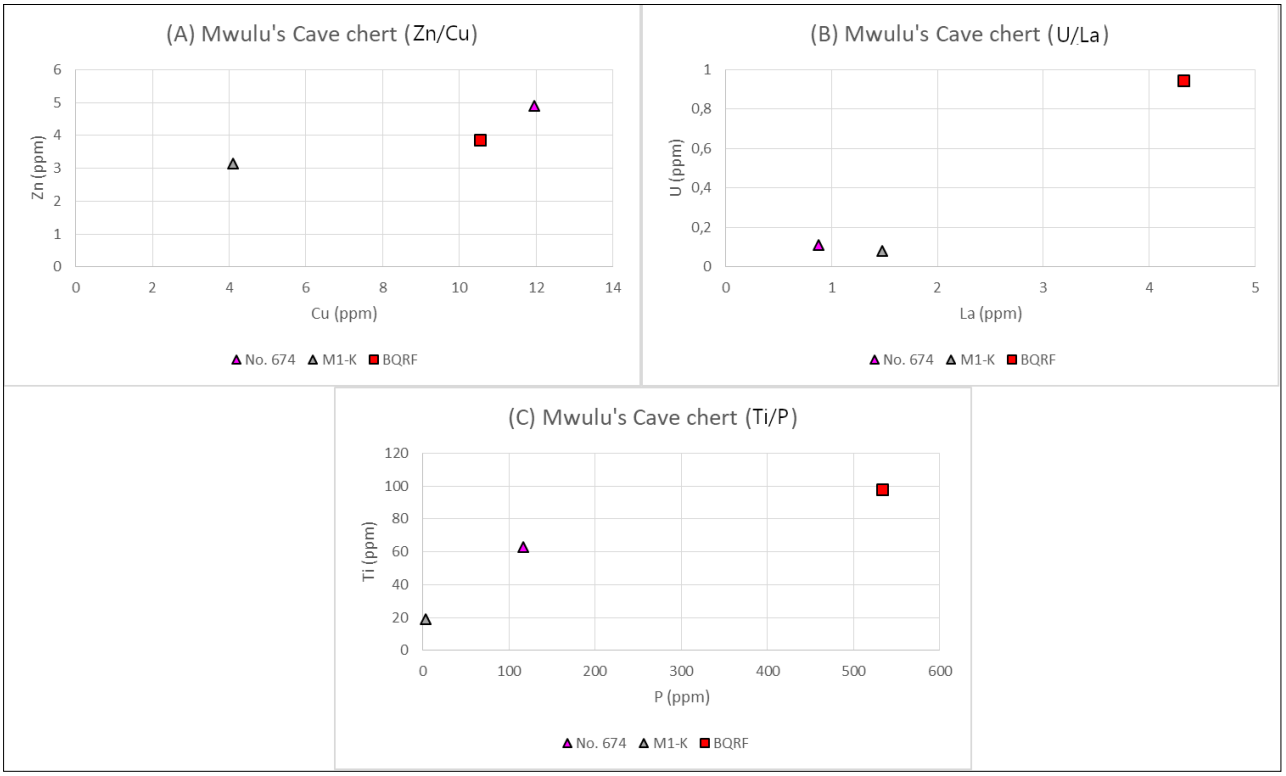

Figure 4.45: A) Zn/Cu, B) U/La, C) Ti/P scatterplots of chert samples at Mwulu's Cave.

5 DISCUSSION

5.1 Provenance

Lithic provenance is defined as the place of origin of a lithic raw material such as a specific outcrop or the geological formation it may belong to. Its provenance also includes the context in which the raw material was obtained. This study uses geochemical analyses (pXRF and ICP-MS) alomg with multivariate PCA analysis to link lithics to formations around OBP and Mwulu's Cave. As mentioned in the results, pXRF is the primary sourcing analysis in this study because it does not damage archaeological material. ICP-MS on the other hand is used in this study to refine some of the pXRF results.

PXRF analysis is the most useful method for determining the provenance of lithics in this study. All the samples (geological and lithic) were analysed through pXRF and comparisons between geological samples from different formations can be made. This makes it possible to see which lithic samples may be closely related to each of the formations. Unfortunately, thin section analysis and ICP-MS, methods that were meant to verify pXRF results, are not as useful as pXRF in this study because only a few samples could be analysed through them. As seen in the discussion below, these methods only support limited results determined through pXRF.

5.1.1 Olieboomspoort Rock Shelter

Rock types

From PCA analyses, only dolerite could be clearly differentiated from the rest of the rock types found around OBP. Quartzite, shale, sandstone, and quartz overlap and are very similar.

Quartzite

The quartzite geological samples around the Mogalakwena Formation and the Cleremont Formation are very similar although CMF samples from the Cleremont Formation have a visible matrix, a characteristic that is not noted in Mogalakwena Formation samples. Based on the pXRF results, it is evident that Mogalakwena Formation geological samples have more diverse Fe, Si, and Mn amounts (PCA) as well as Ti/Fe and Si/Al ratios compared to the Cleremont Formation samples. Mogalakwena Formation samples also have higher Al contents in comparison to the Cleremont Formation samples.

Quartzite is the most abundant raw material in the selected OBP lithic assemblage. Most of the quartzite lithics from OBP seem to relate closer to secondary geological samples collected around the Mogalakwena Formation. The rest of the lithics (<17.9%) seem similar to Cleremont Formation geological samples (CMF and BPC1). This is not supported by PCA which shows an overlap of the two formations. This makes it impossible to determine their exact provenance.

Shale

As mentioned, shale lithics make up about a third of the lithics selected from the OBP assemblage. This observation does not go hand in hand with the number of geological samples noted within the 30 km search area around the shelter. Instead, only two shale samples from OBP 10 near the Mogalakwena Formation were found. Differences between the two geological samples OBP 10A and OBP 10B are noted from macroscopic and pXRF results. OBP 10B is foliated while OBP 10A is not, and pXRF results show that OBP 10B has a higher Al content than OBP 10A (Figure 4.19).

Macroscopic and pXRF results are also similar when it comes to comparing lithics to these outcrop samples. Macroscopic analyses show that lithics No. 4670 and No. 4677 are foliated, which makes them possibly similar to OBP 10B. This is also noted through pXRF because these lithics have high Al contents like OBP 10B and could be closer

related to it than they are to OBP 10A (Figure 4.19). Also based on pXRF results, OBP lithic samples No. 110, No. 1226, No. 106AF, and No. 107 seem to relate to OBP 10A while the rest of the shale lithics may be from either OBP 10A or OBP 10B. Thin section results show that OBP lithics No. 164 and YRS1-D relate closer to one another than they do with OBP 10A because they have chlorite and OBP 10B does not (Figure 4.34). These lithics also lack the cloudy patches and opaque, lichen-like mineralisation noted in OBP 10A. Through ICP-MS analysis we see that lithics No. 164 and YRS1-D relate closer to one another than they do with OBP 10A in scatterplots Zr/La (Figure 4.40 A) and Ni/Cr (Figure 4.40 B). This suggests that they may either be from an outcrop similar to OBP 10B, or a different source entirely. PCA results, however, show that the lithics may not be related to either of these outcrop samples although this is largely affected by the lack of geological samples.

Sandstone

Macroscopically, sandstone geological samples collected around the Mogalakwena Formation can be distinguished from one another because they fall under the 'general', 'friable', or with 'phenoclasts' sandstone groups. PXRF results, however, do not present clear groups within the sandstone geological samples.

Based on the macroscopic results, it is expected that sandstone lithics with phenoclasts (No. 1194 and No. 2402) may be similar to OBP 8B because it also has phenoclasts. This observation is not supported by the pXRF results in scatterplots Ti/Fe (Figure 4.20 A) and Si/Al (Figure 4.20 B). PXRF results also show that the sandstone lithics (especially No. 1286 and No. 2402) may be more closely related to OBP 8 compared to all the other Mogalakwena Formation geological samples. The similarity of the lithics to OBP 8B and OBP 8C is unlikely due to the friable nature of the outcrop samples. They seem to be impractical raw materials for the knapping of tools. Based on thin-section results, No. 1194 and OBP 8A seem similar because they are both greywackes. No. 2402 is a sub-litharenite and cannot be linked to either OBP 7 or OBP 8A using petrography. ICP-MS results contrast the similarity between No. 1194 and OBP 8A and show that No. 2402 may be similar to OBP 7 (Figure 4.41 A to D). PCA results show

that all sandstone lithics, with the exception of No. 1194, may be related to the Mogalakwena Formation.

Dolerite

From the selected OBP lithics, 12.3% are made of dolerite raw materials yet no dolerite intrusions were found within the 30 km search area. Instead, four secondary context geological samples were collected along the Rietspruit River (OBP 4G) and the road (OBP 5A, OBP 5D, and OBP 5E). Macroscopically, only one dolerite group is noted in the OBP lithic selection. This is also presented in the pXRF Ti/Fe (Figure 4.21 A) and Si/Al (Figure 4.21 B) scatterplots.

It is difficult to link most of the dolerite lithics to potential sources through the methods used in this study. PXRF results show that No. 130 and No. 4672 may be closely related to secondary context geological samples collected around the Mogalakwena Formation. This is supported by PCA. Other lithics do not show a possible relation with these geological samples in both the Ti/Fe and Si/Al scatterplots. PCA also shows us that most of the lithics seem unrelated to the Mogalakwena Formation samples. Thin section results only show that No. 458 and OBP 4G are both dolerites. It does not suggest similar provenance because No. 458 has augite and hornblende minerals while biotite is noted in OBP 4G. The textures of the two samples are also different because No. 458 has a uniform texture with laths throughout it while OBP 4G is very fine-grained and has phenocrysts. ICP-MS results support the thin section results because there is not enough information to link the two samples (Figure 4.42).

Quartz

Quartz geological samples from the Mogalakwena Formation and the Cleremont Formation have similar characteristics and are difficult to distinguish from one another. This observation is also noted in the pXRF results because the Mogalakwena Formation sand Cleremont Formation geological samples overlap in both Ti/Fe (Figure 4.22 A)

and Si/Al (Figure 4.22 B) scatterplots. PCA results also support this observation. Mogalakwena Formation samples, however, are more diverse, with higher Fe, Ti, and Al contents.

From pXRF analyses of the two quartz samples (No. 493 and No. 1290) from the selected OBP lithic assemblage and the geological samples found around the site, it is noted that the lithics are likely linked to Mogalakwena Formation pebbles and that they are less likely sourced from pebbles of the Cleremont Formation. Based on PCA, no conclusions on provenance can be reached.

Chert

Chert only covers 1.5% of the selected lithics from OBP. Finding its provenance during the field campaign was unsuccessful therefore no links to the geology can be made. Corcoran *et al.* (2013) does, however, acknowledge over 90% of chert fragments in all Waterberg formations and mentions that it occurs as clasts in Mogalakwena Formation conglomerates.

5.1.2 Mwulu's Cave

Rock Types

Through PCA analyses, it is evident that shale is the most distinguishable of the rock types found around Mwulu's Cave. Quartzite, chert, and quartz overlap and are very similar.

Quartzite

BRQF and Malmani Subgroup quartzite samples are macroscopically similar. In the BRQF quartzite samples, however, one group of banded quartzite made of Outcrop 17 and Outcrop G2B is noted. This is also noted through PCA. This group is not presented in the pXRF scatterplot results. Instead, the BRQF outcrop samples are generally

uniform in the Ti/Fe (Figure 4.28 A and B) and Si/Al (Figure 4.28 C) scatterplots. They can be distinguished from the Malmani Subgroup sample because it has a higher Fe and Al content.

Macroscopically, No. 673 is expected to be similar to the banded quartzite outcrop samples. The pXRF scatterplot results only show that it may be similar to outcrop samples from the BRQF. PXRF results also show that quartzite lithics relate more to BRQF outcrop samples than they do to the Malmani Subgroup outcrop sample. This is also seen in PCA results. It is difficult to link No. 640, No. 1021, and M1-J to outcrop samples using petrography. ICP-MS results do show that Outcrop G2 (especially Outcrop G2A) is a probable provenance for quartzite lithics like No. 640 and No. 1021.

Shale

BRQF, Duitschland Formation, and Malmani Subgroup geological shale samples can be distinguished from one another macroscopically and in pXRF K/Al (Figure 4.29 A) and Zr/K (Figure 4.29 B) scatterplots. PCA results contrasts this observation as these formations are overalapping. BRQF samples have bedding and mica minerals, and Malmani Subgroup samples are darker than Duitschland Formation samples. PXRF shows that the BRQF geological samples have the highest Al and Zr content compared to the other two formations. The Malmani Subgroup samples have diverse Al contents, and the Duitschland Formation samples have the lowest K/Al and Zr/K ratios compared to the other two formations.

Only 12.3% of the selected Mwulu's Cave lithic assemblage is composed of shale. Shale outcrops around the site are abundant, especially to the west of Mwulu's Cave. According to pXRF results, more than 50% of the shale lithics are closely related to Duitschland Formation Shale outcrops compared to those belonging to the Malmani Subgroup and the BRQF. Only M3-D may be closely associated with the BRQF shale. PA-3 may be similar to Malmani Subgroup outcrop samples and M3-B seems similar to Duitschland Formation samples. Thin section analysis shows that M3-E and Outcrop 4A of the Malmani Subgroup are different because M3-E has no foliations and inclusions. It is therefore possible that M3-E may belong to the Duitschland Formation shales as seen

in pXRF results. ICP-MS results are not informative due to the lack of shale samples analysed. PCA results cannot suggest provenance because the formations overlap.

Quartz

Xenomorphic and automorphic quartz is noted from macroscopic analyses although these groups are not presented in pXRF Ti/Fe (Figure 4.30 A) and Si/Al (Figure 4.30 B) scatterplots. The pXRF results only show that BRQF quartz samples have diverse Ti/Fe and Si/Al ratios.

Quartz is the second most used raw material in the selected lithics from Mwulu's Cave (13.6%). Based on pXRF and PCA results, the quartz lithic samples from Mwulu's Cave may have been made from BRQF quartz. The BRQF quartz samples are all *in situ* outcrop samples that are probable provenances for the lithics at Mwulu's Cave.

Chert

BRQF and Malmani Subgoup chert outcrop samples in this study can only be macroscopically distinguished from each other through their occurrences. The chert outcrop samples collected from the BRQF are chert pebbles from conglomerates. Chert outcrop samples from the Malmani Subgroup occur as beds associated with Malmani dolomites. Chert samples from these two formations can also be distinguished from each other through Ti/Fe and Si/Al pXRF scatterplots. The BRQF samples have diverse Ti/Fe and Si/Al ratios compared to the Malmani Subgroup samples, and they have a higher Ti content. PCA results show that the BRQF and Malmani Subgroup samples are similar.

Only 3.7% of the selected lithics from Mwulu's Cave are made of chert. It is difficult to determine through pXRF and ICP-MS whether Mwulu's Cave chert lithics were made from raw materials from the BRQF or the Malmani Subgroup. This is because the Ti/Fe pXRF scatterplot shows that they may be similar to Malmani Subgroup samples while the Si/Al scatterplot shows that they may be similar to the BRQF samples. ICP-MS

results mostly show that the lithics relate more to each other than they do with the BRQF outcrop sample. However, PCA results show that it is difficult to determine the provenance of these lithics.

5.2 Procurement strategies

Raw material procurement involves the strategies employed and the processes that took place for that raw material to be collected. Examples of these processes are the transport of the lithic raw material and distance travelled by hominins to collect it. To establish the procurement strategies used by MSA hominins at OBP and Mwulu's Cave, the distances of the outcrops/geological samples from the sites are used (Table 3.2). I have used similar distances as Schmid *et al*. (2016) to differentiate between local, semi-local, and non-local geological outcrops because their system is based on ethnographic and archaeological obseravtions. Porraz *et al*. (2008) and Will *et al*. (2013) also used similar systems. Local outcrops are 0-5 km from the site, while semi-local and non-local outcrops/geological sources are 6-20 km and more than 20 km from the site, respectively (from Schmid *et al.*, 2016).

5.2.1 Olieboomspoort Rock Shelter

Quartzite

It is important to note that of the quartzite geological and outcrop samples, CMF samples are the only *in situ* sources we came across during the field campaign. Overlapping is noted between Cleremont Formation samples and Mogalakwena Formation samples like those from OBP 4 cobbles. These cobbles may have undergone fluvial transportation down the Rietspruit River from CMF, or similar Cleremont Formation outcrops, to the area immediately around OBP. Considering the presence of quartzite lithics that have visible cortices (No. 1195; No. 488; No. 143; No. 3474; and No. 3478) and the abundance of rounded quartzite pebbles and cobbles observed and collected close to OBP, I assume that the majority of quartzite raw material was

procured along the Rietspruit River in the MSA. This assumption is also based on the fact that over 80% of the quartzite lithics are closely related to Mogalakwena Formation secondary sources, the formation in which OBP is found.

Secondary context geological samples from the Mogalakwena Formation like OBP 1 and OBP 4 are less than 1 km from the site with the closest sample being only 130 m from the shelter. The CMF outcrop of the Cleremont Formation lies about 14.4 km from the site. BPC1 pebbles (A, B, C, and F), possibly the least used quartzite raw material, are located 28-29 km from the site. From this quartzite analysis, we can see that MSA hominins who occupied OBP may have mostly procured secondary context quartzite raw materials within a distance of about 1 km from the site. This procurement strategy is similar to that of MSA hominins who collected quartzite raw materials less than 10 km from Diepkloof Rock Shelter during MIS 5. They also procured quartzite raw materials from alluvial terraces in secondary contexts (Porraz *et al*., 2020).

Shale

OBP 10 shale geological samples were located 13-14 km from the shelter. Due to the absence of *in situ* shale outcrops, the scarcity of shale geological sources around the site, and the distance at which they were located from the site, the provenance of the raw material is difficult to establish. The MSA hominins at OBP may have procured the shale raw materials from localities beyond the OBP search area in the Mogalakwena Formation. Non-local raw materials were also procured to make shale lithics (low frequency) at Hoedjiespunt 1 in the MSA (Will *et al*., 2013).

Sandstone

OBP 8 is an *in situ* sandstone outcrop on the same Mogalakwena Formation hill as OBP. It is located within a 1 km distance from the site (155 m from the shelter). From these observations, we can assume that MSA hominins at OBP often procured sandstone raw materials from primary contexts close to the shelter in the Mogalakwena Formation.

Dolerite

Considering No. 130 and No. 4672, there is a possibility that the secondary context samples collected near the Mogalakwena Formation are similar to these lithics. OBP 5 samples were collected 9 km from the site while OBP 4G is the only dolerite sample found within 1 km of the shelter. Fourie *et al*. (2014) mentioned the difficulty of locating dolerite outcrops but does not claim it to be impossible. Based on the dolerite observations at OBP, MSA hominins either found an inconspicuous dolerite outcrop close to OBP 5 (9 km away) and collected secondary context dolerite around it, or they procured the raw material from secondary contexts along the river close to the site.

Quartz

Of the quartz pebbles that are possible provenance of No. 493 and No. 1290 lithics, OBP 3B is the only pebble collected from an *in situ* conglomerate in the Mogalakwena Formation. For this reason, quartz pebbles around this outcrop may have come from it. These pebbles, including the *in situ* outcrop, are located within 1 km from the site while OBP 5C and OBP 10E were collected 9 km and 13-14 km from the site, respectively. No. 493 has a cortical surface resembling that of the quartz pebbles found along the Rietspruit River close to OBP. Based on these observations, MSA hominins occupying OBP may have procured quartz pebbles along the Rietspruit River as a raw material for quartz lithics. Quartz raw materials from Hoedjiespunt 1 were also procured locally from secondary contexts in the MSA (Will *et al.,* 2013).

Chert

The low amount of lithics in the selected assemblage (and the full assemblage: Val *et al*., 2021) may suggest that the MSA hominins at OBP may have also had difficulty procuring chert raw materials or that they just did not prefer it.

5.2.2 Mwulu's Cave

Quartzite

BRQF quartzite outcrop samples were located in *in situ* contexts and none of the selected quartzite lithics in the Mwulu's Cave assemblage have visible cortical surfaces (de la Peña *et al*., 2019). For this reason, it is deduced that the raw material for lithics was procured in primary contexts (*in situ* outcrops). Outcrop 16, Outcrop 17, and Outcrop G2 are located within 1 km of Mwulu's Cave with the closest being Outcrop 16 at the cave and the furthest being Outcrop G2 only 32 m away. Outcrop 21A was sampled 3.7 km from the site. Based on these findings, MSA hominins at Mwulu's Cave mostly procured quartzite raw materials from *in situ* outcrops at the site and/or very close to it. The same procurement strategy was used by MSA hominins at Elands Bay Cave (Schmid *et al*., 2016). They procured quartzite raw materials from the cave itself and less than 5 km around it (Schmid *et al*. 2016).

Shale

All of the shale sources around Mwulu's Cave, except Outcrop 6 and Outcrop 8, are *in situ* outcrops, and none of the 10 shale lithics in the selected sample have a visible cortical surface. Therefore, the shale used to make the lithics could have been obtained from primary contexts. The Duitschland Formation shale outcrops Outcrop 1 and Outcrop 2 are 9.9 km and 9 km away from Mwulu's Cave respectively. The Malmani Subgroup shale outcrops that like Outcrop 3, Outcrop 4, and Outcrop 8 are located 8.2 km, 7.6 km, and 4.6 km from the site, respectively, although Outcrop 8B is a secondary context sample and an unlikely source. The only probable BRQF shale samples, based on pXRF results, are from Outcrop 14 (A and B). Outcrop 14 is only 378 m away from the cave. Based on these observations, MSA hominins at Mwulu's Cave may have preferred and procured Duitschland Formation shales from almost 10 km away from the site even though shales from other formations were closer to the site.

Quartz

As mentioned, the outcrop BRQF samples were collected from primary contexts. The samples from Outcrop 16 were collected from the cave, those from Outcrop 19 from 51 m from the site, and those from Outcrop 20 and Outcrop 21 were collected 3.7 km from Mwulu's Cave. These observations suggest that the MSA hominins at Mwulu's Cave probably procured *in situ* quartz raw materials either from the cave or from the mountain adjacent to it less than 5 km away. Quartz raw materials at Elands Bay Cave were procured using the same strategy in the MSA. They were procured locally from primary contexts (Schmid *et al.*, 2016).

Chert

The chert outcrop samples from around Mwulu's Cave were collected from *in situ* contexts. Malmani Subgroup samples were collected 8.2 km and 7.6 km from Mwulu's Cave while those from the BRQF were collected 760 m from the site as well as at the site itself. The low number of chert lithics in this study's selection makes it difficult to determine if MSA hominins at Mwulu's Cave procured the chert raw materials close to the site or if they travelled to Malmani Subgroup to get them. Therefore they may be collected locally or semi-locally from *in situ* chert sources. At Elands Bay Cave a similar procurement strategy is noted. MSA hominins procured chert raw materials semi-locally at the Redelinghuys outcrop five to 20 km from the site (Schmid *et al*., 2016). This finding, however, is contrasted by that of Will *et al.* (2013). They found that chert raw materials at Hoedjiespunt 1 were procured non-locally in the MSA.

5.3 Closing remarks for provenance and procurement strategies at Olieboomspoort Rock Shelter and Mwulu's Cave

A few questions on the provenance and procurement of shale and chert raw materials at OBP remain unanswered in this study. Shale occurs as the second most used raw

material at OBP but its outcrops and geological sources seem few and/or far. Chert, albeit the least used raw material, occurs in the lithic assemblage but we were unable to locate any geological sources. Perhaps these raw materials, especially shale, were collected from areas beyond the search area used in this study. Another observation is that quartzite was preferred over quartz raw materials even though quartz pebbles were equally available along the Rietspruit River close to the site. This is also seen at Elands Bay Cave where the MSA hominins of 'MSA1' preferred quartzite over quartz because of its characteristics (hardness, durability, etc.) (Schmid *et al*., 2016). The same is possible for the MSA hominins at OBP. Generally, however, the MSA hominins of OBP procured quartzite and quartz raw materials locally from along the Rietspruit River. Sandstone may have been procured locally close to the site. Dolerite raw materials may have been collected along the Rietsprit River in a secondary context although it is more likely that they procured this raw material from unknown dolerite outcrops. Shale may have been procured semi-locally and/or non-locally from outcrops that are unknown and the provenance of chert lithics is also unknown.

The Rietspruit River may have provided many of the lithic raw materials that were used at OBP in the MSA. It is a left-bank tributary of the Mokolo River which flows in a northerly direction towards the Limpopo River. The Rietspruit River flows over the Waterberg Group (particularly the Mogalakwena Formation) conglomerates, shales (Barker *et al*., 2006) sandstone sheets (Eriksson *et al*., 2008). Quartzite, quartz, and chert from conglomerates, as well as shale and sandstone raw materials, could have been transported downstream towards the site and procured along the river by MSA hominins at OBP. Based on measurements from the sketch map of the Mokolo River catchment area (Figure 5.1) and the 2326 Ellisras geological map (Figure 5.2), the dolerite outcrop is situated about 3 km (local) outside the catchment area. This means that MSA hominins at OBP possibly travelled to dolerite outcrops to procure it.

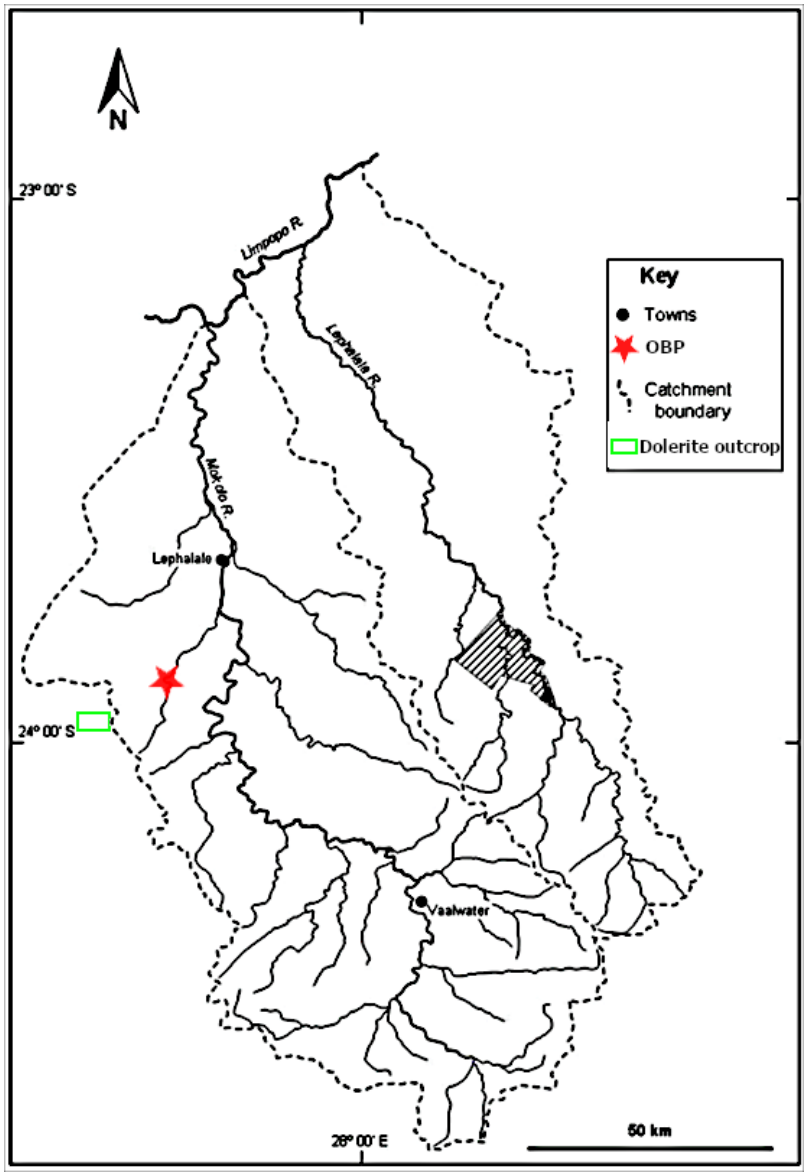

Figure 5.1: Sketch map of the Lephalale and Mokolo River catchments. OBP is represented by the red star and the location of the closest dolerite outcrop is in the green box (modified from Oberholster *et al.*, 2010).

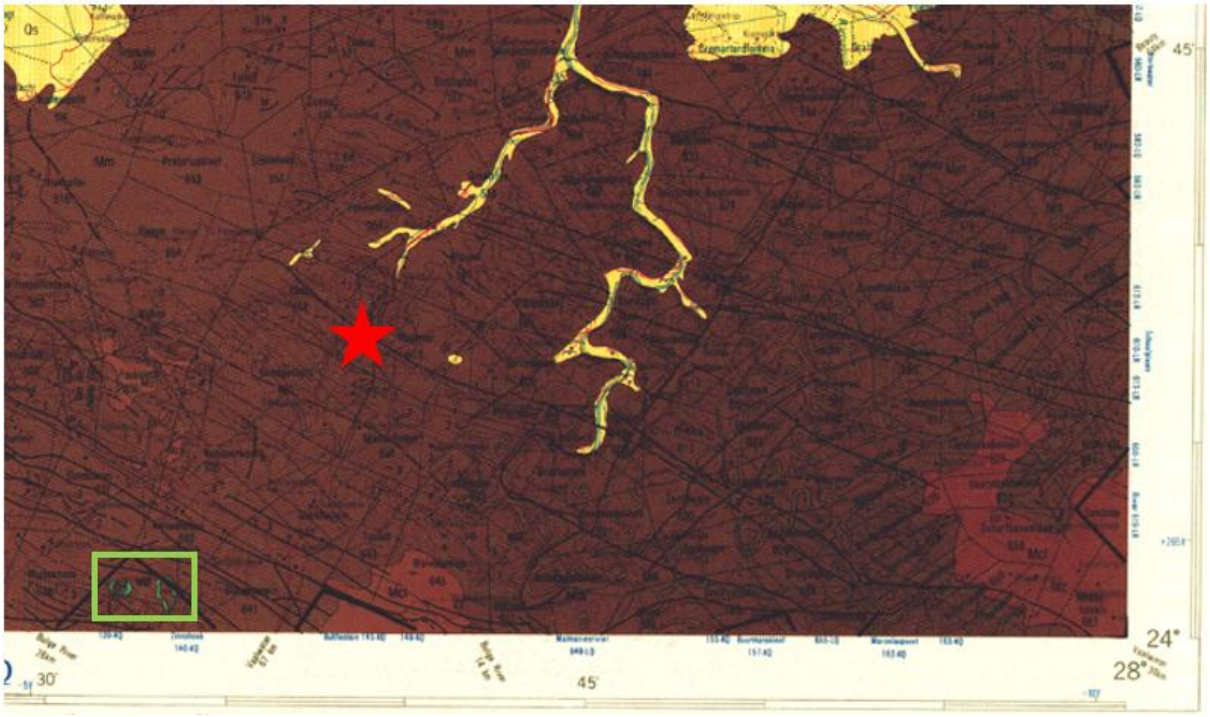

Figure 5.2: Section of the 2326 Ellisras geological map showing the position of the dolerite outcrop in relation to OBP in the Moloko River catchment area (red star) (Geological Survey (South Africa) and Besaans, 1959).

Based on the selected lithic assemblage from Mwulu's cave, quartzite may have been used more than shale at the site in the MSA. This could be due to the abundance of quartzite at the cave and close to it. Quartz is also prominent in the assemblage, although not many outcrop sources were located around the site. This study shows us that MSA hominins at Mwulu's Cave predominantly procured local, *in situ*, lithic raw materials. Chert and shale, however, may have been procured semi-locally.

Mwulu's Cave is 15 m above the base of a cliff in a valley and no rivers are noted near the site. Therefore, lithic raw materials (i.e. quartzite, quartz, shale, and chert) must have been brought to the site by MSA hominins.

A few lithic raw material procurement analysis studies have been conducted at sites in South Africa. Some examples of these studies are those of Porraz *et al*. (2020), Mackay *et al*. (2022), Schmid *et al*. (2016), and Will *et al*. (2013) among others. The current study is similar to these although a combination of petrologic, petrographic, and

geochemical methods is used to analyse both lithics and outcrop samples from OBP and Mwulu's Cave.

OBP and Mwulu's Cave are sites once placed under the Pietersburg Industry. According to Wadley (2015), this industry is characterised by quartzite raw materials, among others, that can be determined by local geology. This statement is supported by the results of the current study. Both OBP and Mwulu's Cave have lithic assemblages dominated by the quartzite raw material and this raw material is indeed represented in the local geology around the sites. Schmid *et al.* (2016) stated that during MIS 6 and MIS 5 hominins procured local raw materials for lithic production and this statement is partially true for OBP and Mwulu's Cave. Based on the selected lithic samples in this study, possibly more than 50% of the lithic raw materials at OBP and Mwulu's Cave were procured locally within 5 km of the sites. Similar procurement strategies are noted at MSA sites like Elands Bay Cave (Schmid *et al*., 2016), Diepkloof Rock Shelter (Porraz *et al*., 2020), and Hoedjiespunt 1 (Will *et al*., 2013) in South Africa. The MSA sites beyond South Africa (those cited in this study), however, show generally non-local procurement strategies. Examples of these African sites include those in the Olduvai Gorge (Favreau *et al*., 2020), the Olorgesailie basin (Brooks *et al.,* 2018), and at the White Paintings Shelter (Nash *et al*., 2013).

5.4 Limits of the study and recommendations for future studies

Unfortunately, this study could not determine the exact provenance of each of the lithics from OBP and Mwulu's Cave. Only preliminary provenance results and procurement hypotheses are available. These are obtained from macroscopic and pXRF analyses because not enough materials could be analysed using thin section and ICP-MS destructive methods- methods that were meant to verify the pXRF results. In future studies, more samples will have to be analysed through thin sections and ICP-MS to fulfil the aim of this study.

Shale, dolerite, and chert outcrops around OBP were not located during the prospection survey of this study. This makes it difficult to determine the provenance (and therefore procurements strategies) of some lithics from OBP. A more extensive search area

around the site may be required to locate these outcrops. This may also require organising access to some of the private properties around OBP. I acknowledge that one of the reasons for inconclusive results in this study was the lack of samples to analyse. Therefore more geological samples should also be collected in future studies in order to obtain more robust and reliable results. This study may have not produced positive results, but the methodology will be useful for future studies.

6 CONCLUSION

Raw material macroscopic, pXRF, thin section, and ICP-MS analyses determined that hominins at OBP and Mwulu's Cave may have predominantly procured lithic raw materials locally (following the definition of Schmid *et al*., 2016). This is a common observation at other MSA sites in South Africa too (Elands Bay Cave (Schmid *et al*., 2016), Diepkloof Rock Shelter (Porraz *et al*., 2020), and Hoedjiespunt 1 (Will *et al*., 2013)).

At OBP, all of the raw materials (except chert) may have been procured around the Mogalakwena Formation. Quartzite and quartz were possibly procured locally in secondary context from the Rietspruit River. Sandstone may have been collected locally from *in situ* outcrops within the Mogalakwena Formation. Shale seems to have had a non-local procurement, while dolerite may have been sourced from the Rietspruit River, although an unknown outcrop may be the source. Chert raw materials are unknown.

At Mwulu's Cave, quartzite, and quartz may have been procured from the BRQF, and shale from the Duitschland Formation. All the raw materials were probably procured from *in situ* outcrops. Quartzite and quartz from Mwulu's Cave were procured locally while shale may have been procured semi-locally. It is uncertain whether chert was procured locally or semi-locally.

This study has provided preliminary provenance and procurement information about lithics from OBP and Mwulu's Cave although more petrographic and ICP-MS analyses are required to verify these findings in future studies.

White quartzite (Figure A1)

No. 143

A fine to medium-grained white quartzite with a smooth, polished texture and shiny lustre. It has a dull, red-brown cortex. The grains are annealed and no matrix is visible. 5% of the rock is represented by sub-angular black grains (0.25 mm).

No. 488

A white quartzite with a smooth texture and shiny lustre. Its weathered surface is red and its fresh surface is white. The quartz crystals are annealed and no matrix is noted.

No. 494

A crystalline, fine-grained quartzite with a red weathered surface. It has a smooth texture and a shiny lustre. Sub-angular quartz crystals are noted in a white matrix (5%).

No. 468

A coarse-grained quartzite pebble with a smooth red weathered surface and pink fresh surface. It has a dull lustre through which some grain foliation is noted. The quartz crystals are annealed and no matrix is noted.

No. 1873

A white quartzite rock with heavy calcite coating. It is rough and has a dull texture.

No. 1795

A heavily coated sample that appears to be a brown-white quartzite. The fine to medium (0.2-0.5 mm) quartz grains are rounded and no visible matrix is noted.

No. 486

A grey-white quartzite with a rough texture and shiny lustre. It is fine-grained (<1 mm) with sub-rounded white and clear grains in a white matrix (10%).

No. 2332

A grey-white quartzite with fine to medium (0.2-0.5 mm) quartz grains. It has a smooth texture and dull lustre. The crystals are sub-rounded to rounded and no visible matrix is noted.

No. 3478

A very heavily coated, quartzite with sub-angular and sub-rounded, medium sized quartz grains.

No. 4678

A crystalline, red-brown (white fresh surface) quartzite with a rough texture and dull lustre. It has sub-angular, medium to coarse quartz grains that are interlocking. Less than 15% matrix is noted. Clear, yellowish staining is present around some grains.

No. 2374

Grey-white quartzite that is heavily coated in calcite. It has a smooth texture and a dull lustre. The sample is coarse-grained (2-4 mm) with sub-angular to angular, annealed quartz grains.

No. 120

A pink-white quartzite with medium to coarse-grained (0.5- 1 mm) in a black and white matrix (15%). The quartz and microcrystalline grains are mostly sub-rounded to rounded although the larger grains are generally sub-angular.

CMF1

A white quartzite sample with an orange weathered surface. It has medium to coarse (0.5-1 mm) quartz grains that are rounded, and pink and grey in colour. A white matrix is noted (10%). There is a 1-1.5 cm coarser banding through the finer material (2-4 mm) which brings in an orange and purple colour.

CMF2

A white quartzite with an orange weathered surface, sampled from the Cleremont Formation. It has a granular texture and an upward coarsening trend is noted. It is coarse-grained (1-3 mm) with rounded quartz grains in a white matrix (10%).

BPC1B

A white quartzite with a smooth surface and a dull lustre. It is a rounded pebble, around 6.5 cm, with a pink-brown weathered surface. The medium to coarse (0.5 mm) quartz grains are annealed and no matrix is noted.

OBP4 F

A smooth and dull quartzite pebble (3.5 cm) with an orange cortex. The white grains are annealed and no matrix is visible.

OBP5 B

A rounded, quartzite cobble with a rough, orange weathered surface. The grains are coarse (0.6-1 mm) and interlocking. No matrix is noted

OBP6 A

A rounded, white quartzite cobble (10 cm) with a smooth texture and a dull lustre. The weathered surface of this sample is orange and its coarse grains (1-3 mm) are interlocking. No matrix is noted.

OBP6 B

This coarse-grained (1 mm), white quartzite cobble (7.8 cm) has a rough, red cortex and a dull lustre. Its grains are sub-rounded to sub-angular and are interlocking with each other. No matrix is noted

OBP10 D

A black and white quartzite pebble that is rounded and has a smooth cortex. It has a dull lustre and has coarse quartz grains (0.8-1 mm) that are annealed. No matrix is noted.

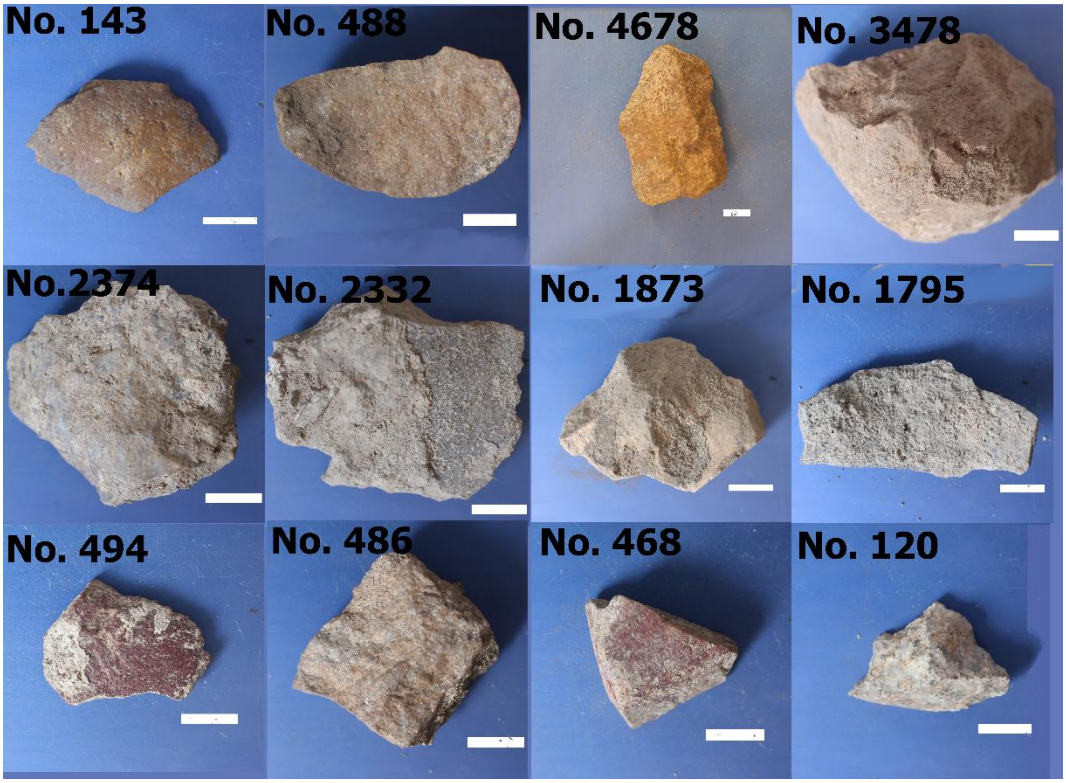

Figure A1*: White quartzite lithics from OBP.*

Red quartzite (Figure A2)

No. 2353

A red quartzite sample with a smooth texture and a shiny, crystalline lustre. The grains are interlocking and no matrix is noted. There is calcite coating

No. 3474

A red quartzite with a rough texture and shiny, crystalline lustre. The fine to medium sized (~0.2 mm) quartz grains are annealed and no matrix is visible.

No. 4671

A red quartzite with a smooth red weathered surface (pebble cortex) and a rough, crystalline fresh surface. The sample has a dull lustre and is coarse-grained with grain sizes going from 0.5 mm to 1mm. It has red, pink, white and black (in decreasing order), sub-rounded grains in a brown matrix (30%).

No. 4683

A dark red quartzite with a rough, crystalline texture and a shiny lustre. It has interlocking, angular, medium sized quartz grains (<0.5 mm) and no matrix is noted.

No. 4697

A red-brown quartzite with a rough, crystalline texture and a shiny lustre. It has annealed quartz grains (the grain boundaries are not visible under the binocular microscope) and no matrix is noted.

No. 4695

A crystalline, red quartzite with a rough texture and shiny lustre. It is fine to medium-grained (0.1-0.3 mm). The grain shape is angular and a few grains are dark red. No matrix is noted.

YRS1-C

The rock is generally red with a rough texture and a dull lustre. It has fine to medium, sub-rounded grains that grade from black, to white, to red across the sample. No matrix is noted.

YRS1-E

A dark, red-brown quartzite pebble with a smooth cortex. It has a smooth texture and dull luste. The medium to coarse (0.3-0.7 mm) quartz grains are glassy, angular, and interlocking. No matrix is noted.

No. 1195

The fresh surface of this sample is heavily coated with calcite. The weathered surface, however, is clear and shows a smooth, red cortex. The grains in this rock are sub-angular, coarse, and interlocking. No matrix is noted.

BPC1A

A rounded quartzite pebble that spans up to 6.5 cm longitudinally and has a smooth, orange weathered surface and a dull lustre. It looks crystalline on the fresh surface. The pink/red quartz grains are coarse (0.7 mm) and annealed. No matrix is noted.

BPC1C

A red, rounded quartzite pebble (6.5 cm) with a smooth texture and a dull lustre. It has a white and dull brown cortex. The quartz grains are coarse (0.5-0.9 mm) and sub-rounded. They are also interlocking and annealed in some places. No matrix noted.

OBP4 A

A large, rounded, quartzite cobble (ex situ; 15 cm) with a brown weathered surface and a pink fresh surface (red and white). It has medium to coarse (0.5-1 mm) quartz grains that are annealed. No matrix is noted

OBP4 C

Quartzite pebble (5 cm) with an orange, pitted, weathered surface and a red fresh surface. The grains are annealed (cannot see grain boundaries) and no matrix is noted.

OBP4 E

A rounded, quartzite cobble (10.5 cm) with a rough, orange cortex and red, coarse (1-2 mm), annealed quartz grains. The cortex is weathered and dull. No matrix is noted.

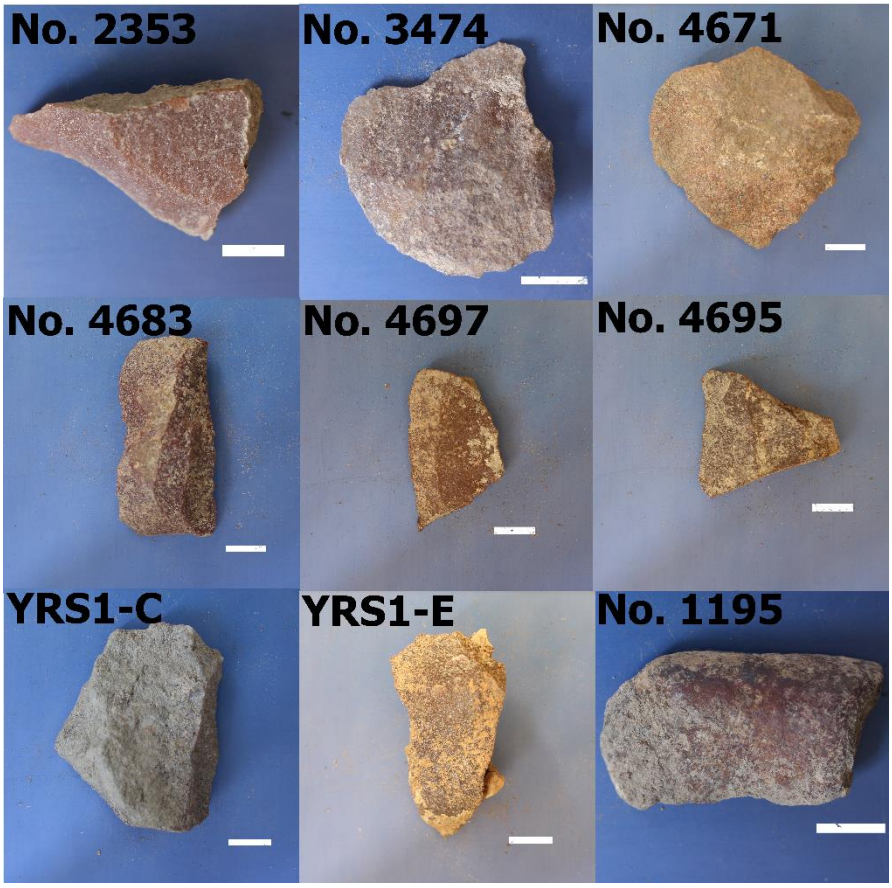

Figure A2*: Red quartzite lithics from OBP.*

Black quartzite (Figure A3)

No. 440

A black quartzite with calcite coating on one side. The rock has a shiny lustre with annealed black and grey, medium to coarse (<2 mm) quartz crystals. Green minerals (possibly chlorite) are noted across the sample. No matrix is noted.

No. 1824

A red-black, coarse-grained (0.5-1 mm) quartzite that is heavily coated in calcite. It has a rough texture and dull lustre.

No. 2358

A coarse-grained (>4 mm), multi-coloured quartzite (red, black and white crystals) sample with calcite coating. It has a rough texture and glassy lustre. The grains are sub-rounded and poorly sorted in a white matrix (25%)

No. 2364

A black quartzite sample that is rough to touch and has a glassy lustre. It has coarse (0.5-1 mm) sub-angular to sub-rounded interlocking quartz grains. No matrix is noted.

No. 106

A heavily coated, red-black quartzite with a dull lustre and rough texture where visible. The grains are fine and sub-angular in a brown matrix (15%).

BPC1F

A rounded, black quartzite pebble (4.5 cm) with a smooth texture and a dull lustre. It has black and grey quartz grains that are sub-angular and coarse (1-2 mm). These grains are annealed and interlocking. No matrix noted.

OBP6 F

A black, coarse-grained (1 mm) quartzite with a smooth, crystalline, fresh surface and a dark, greenish-grey weathered surface. The quartz grains are angular and annealed. No matrix is noted.

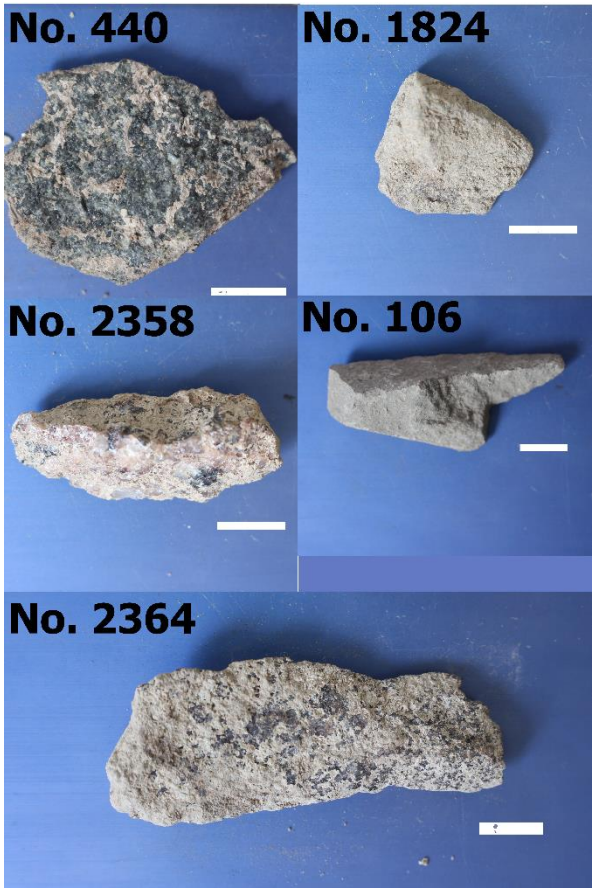

Figure A3*: Black quartzite lithics from OBP.*

Shale/meta-sedimentary samples (General) (Figure A4)

No. 106 Af

A coated red-brown meta-sedimentary rock with a smooth texture and dull lustre. The weathered surface is orange and dark brown patches are visible throughout the rock. The rock is very fine-grained and the grains cannot be seen under the binocular microscope.

No. 106 BB

A brown meta-sedimentary rock with a smooth texture and dull lustre. The rock is very fine-grained and the grains cannot be seen under the binocular microscope.

No. 1968

A very fine-grained, brown meta-sedimentary rock with a smooth texture and dull lustre.

No. 107 Au

A red-purple-brown very fine-grained meta-sedimentary rock with a rough texture and dull lustre.

No. 4682

A dark green-grey meta-sedimentary rock with an orange-brown weathered surface. It is very smooth to touch and has a dull lustre. The grains in the sample cannot be seen.

No. 122

A crystalline, grey-black, meta-sedimentary rock that is heavily coated with calcite precipitation. It has a rough texture and dull lustre with coarse (0.5- 1 mm), sub-rounded grains. Not much is visible about the relationship between the grains due to coating.

No. 1789

A red-brown, very fine-grained meta-sedimentary rock with a smooth texture and dull lustre. Looks like a river calcrete in ferruginous coating.

No. 110

A coarse-grained (0.5-1 mm) sample with a purple and green-black weathered surface. It is very hard to see the fresh surface although the grains seem rounded and no matrix is noted.

No. 164

A very fine-grained (cannot see individual grains), black rock. The sample has a smooth surface and dull lustre. There is calcite coating on the cortex of the rock.

No. 159

A black, light weight shale that is very fine-grained, has a smooth texture and a dull lustre.

YRS1-D

A red-brown, very fine-grained sample with a black weathered surface. The sample is smooth textured and has a dull lustre.

No. 142

A calcite coated, black shale with foliation noted in the sample. Its texture is very fine-grained (silt sized grains) and smooth with a dull lustre.

No. 420

A very fine-grained (grains cannot be seen with the naked eye), red-black shale with calcite coating. It has a rough texture and dull lustre.

YRS1-A

A black, very fine-grained (grains are not visible) shale with a smooth texture and a dull lustre.

OBP10 A

A very fine-grained, purple-grey, meta-sedimentary rock that has a smooth texture and a dull lustre.

Figure A4: Shale (general) lithics from OBP.

Shale with inclusions (Figure A5)

No. 106 A2

A red-brown meta-sedimentary rock with a smooth texture and dull lustre. The grains are very fine although sparse white (0.5-1 mm) and black angular (0.5-2 mm) grains are noted throughout the sample (10%).

No. 1226

A red-brown fine-grained rock with a rough texture and a dull lustre. Dull, black patches are noted throughout the sample (45%).

No. 2290

A very fine-grained, dark green-grey rock with a smooth texture and dull lustre. The sample has black crystals dispersed throughout the sample (5%).

No. 137

A heavily coated rock that appears to be a black shale in places where the coating has cracked. It has very fine grains that are barely visible with the naked eye and has a dull lustre. Red grains are noted within the black matrix.

YRS1-B

A red-black, very fine-grained shale with a smooth texture and dull lustre. It seems there are red sub-angular grains in a black matrix (40%).

No. 4684

A very fine-grained, grey-black shale with a smooth texture and dull lustre. It has red-orange coating/staining in some areas. The sample is speckled with pitch-black crystals.

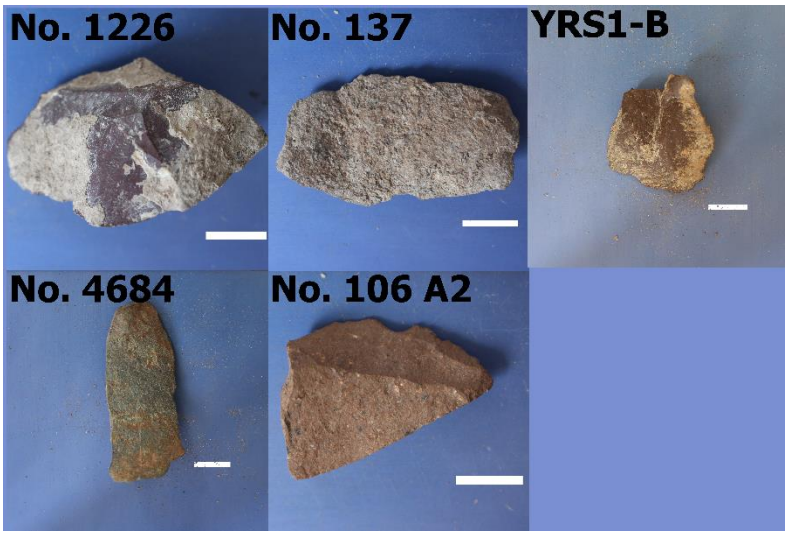

Figure A5: Shale lithics with inclusions from OBP.

Shale with foliation (Figure A6)

No. 4670

A meta-sedimentary rock with an orange-brown fresh surface and a red-brown weathered surface. It is very fine-grained (silt sized), has a smooth texture, and a dull

lustre. A foliation that almost looks like cleaving is noted on the sides of the sample (where it is not coated in calcite).

No. 4677

A very fine-grained shale or meta-sedimentary sample with a smooth texture and dull lustre. The sample has alternating banding (black, brown and light grey) on its fresh surface and is all black on its weathered surface. Small, shiny micas are noted throughout the sample (20%).

OBP10 B

A black, very fine-grained shale with a rough texture and a dull lustre. Some foliation is noted on the edges of the sample.

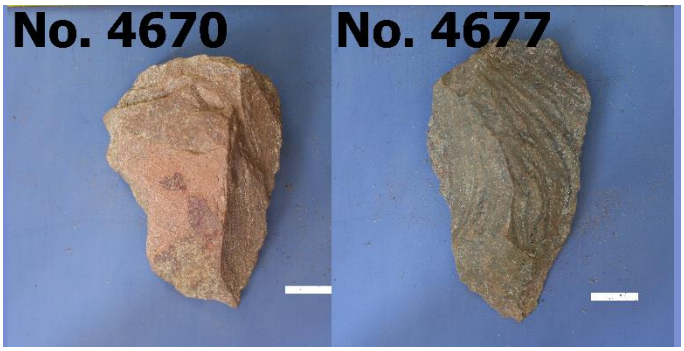

Figure A6: Shale lithics with foliations from OBP.

Sandstone (General) (Figure A7)

No. 1286

A light brown (possibly stained by sand) sandstone with a rough texture and dull lustre. It has fine to medium (0.5 mm) sub-rounded grains in a brown matrix (10%).

No. 2395

A heavily coated (calcite), light brown sandstone with a rough texture and dull lustre. The fine to medium (0.1-0.5 mm), sub-angular grains interlock in a barely visible matrix (<5%). Some black crystals (0.05 mm) are noted in small clusters throughout the sample.

No. 3486

A heavily coated, red sandstone with a rough texture and dull lustre. It has medium-grained (0.4-0.6 mm), sub-angular quartz crystals and no matrix is noted.

No. 2366

A coarse-grained, black sandstone (0.5-2 mm, with a few red and white grains) with a rough texture and glassy lustre. It has sub-rounded grains in a white matrix (5%).

OBP3 C

A sandstone sample that has coarse-grained beds alternating with a black oxidised beds. The first coarse (1-5 mm) sandstone bed has black, pink and grey quartz grains in a white matrix (15%). These are sub-rounded to sub-angular. The second sandstone bed is uniform and has finer, quartz grains (0.5 mm) in a white matrix (10%). These grains are sub-angular and red in colour. The black oxidised bed is similar to second sandstone.

OBP7

A black, coarse-grained (0.7-1 mm) sandstone with a glassy quartz, fresh surface and a dull, brown weathered surface. The quartz grains are angular and interlocking. No matrix is noted.

OBP8 A

A banded sandstone with a rough texture and a dull weathered surface lustre. It was sampled from a 1m thick, in situ, outcrop. The fresh surface has a glassy lustre. This sample has black (2 cm) and red (1 cm) banding. The black layers are fine-grained and the red layers have a coarse texture (2-8 mm). The grains throughout the sample are sub-angular and interlocking, and no matrix is noted.

OBP8 C

An oxidised sandstone sample that is friable and has a rough texture and a dull lustre. It is composed of coarse (3-5 mm), sub-angular, grains in a brown matrix (10%).

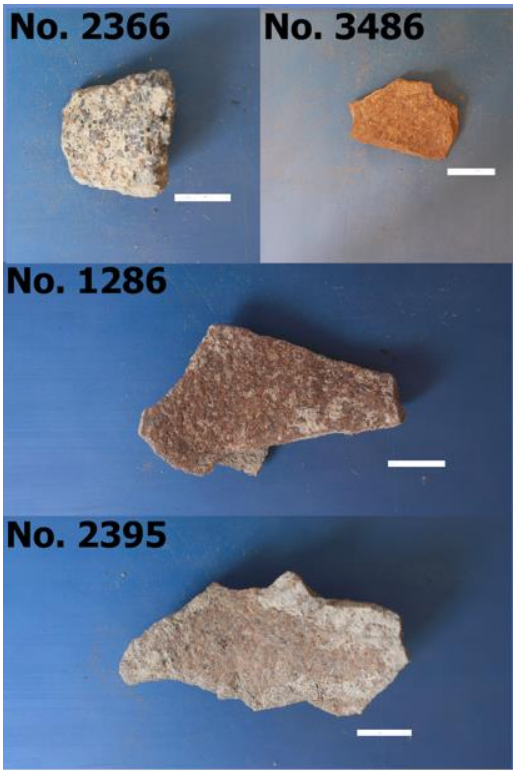

Figure A7: Sandstone (general) lithics from OBP.

Sandstone with phenoclasts (Figure A8)

No. 1194

A dark, red-brown sandstone that is smooth to touch and has a dull lustre. The sample is heavily coated with calcium carbonate. It is very fine-grained (grains are not visible to the naked eye) with a larger grey quartz grain (<1 mm) and black, shiny mica crystals (0.5 mm).

No. 2402

A red-black sandstone with a rough texture and a dull lustre. The grains are mostly black but red and white grains are evident. These are angular and interlock tightly, leaving no visible matrix. Larger quartz grains (phenoclasts) noted among the interlocking grains.

OBP8 B

A friable sandstone sample with an oxidised layer and red sandstone layer. These are both coarse-grained (0.5-2 mm) and a few quartz pebbles (5-8 mm) are caught in sandstone.

Figure A8: Sandstone lithics with phenoclasts from OBP.

Banded sandstone

OBP3 C

A sandstone sample that has coarse-grained beds alternating with a black oxidised beds. The first coarse (1-5 mm) sandstone bed has black, pink and grey quartz grains in a white matrix (15%). These are sub-rounded to sub-angular. The second sandstone bed is uniform and has finer, quartz grains (0.5 mm) in a white matrix (10%). These grains are sub-angular and red in colour. The black oxidised bed is similar to second sandstone.

OBP8 A

A banded sandstone with a rough texture and a dull weathered surface lustre. It was sampled from a 1m thick, in situ, outcrop. The fresh surface has a glassy lustre. This sample has black (2 cm) and red (1 cm) banding. The black layers are fine-grained and the red layers have a coarse texture (2-8 mm). The grains throughout the sample are sub-angular and interlocking, and no matrix is noted.

Friable sandstone

OBP8 B

A friable sandstone sample with an oxidised layer and red sandstone layer. These are both coarse-grained (0.5-2 mm) and a few quartz pebbles (5-8 mm) are caught in sandstone.

OBP8 C

An oxidised sandstone sample that is friable and has a rough texture and a dull lustre. It is composed of coarse (3-5 mm), sub-angular, grains in a brown matrix (10%).

Dolerite/igneous (Figure A9)

No. 1241

A heavily coated, aphanitic, black dolerite with a rough texture and dull lustre. White plagioclase feldspar laths are speckled across the black matrix.

No. 4672

An aphanitic, black dolerite with a rough texture and dull lustre. It has white plagioclase feldspar laths throughout the sample that are more than 2 mm long.

No. 458

A dark grey rock with a smooth texture and dull lustre. It is probably igneous in nature. This aphanitic rock has fine white plagioclase feldar laths (55%) in a black matrix (45%).

No. 408

A heavily coated (calcite) black rock with a rough texture and dull lustre. The grains are very fine to medium-grained but white plagioclase feldspar laths (1 mm, 30%) are noted in the black matrix.

No. 489

N aphanitic, green-black rock (possibly igneous) with a rough texture and dull lustre. It has some degree of foliation throughout the sample.

No. 182

An aphanitic rock with a red-brown weathered surface and black fresh surface. The lustre is dull and the texture of the rock is smooth. Cream white plagioclase feldspar laths (0.2-0.5 mm) are noted throughout the rock (20%).

No. 4688

A red-black rock with a rough texture and a dull lustre. It has coarse (-0.6 mm), angular grains and no matrix is noted.

No. 130

A heavily coated, black rock with a rough (bumpy) texture and dull lustre. The grains are coarse and rounded. As with the previous rock, the relationship between grains is difficult to see.

OBP4 G

An aphanitic, dolerite sample with a black fresh surface and a rough, dull brownish-black weathered surface. The fresh surface is black and smooth.

OBP5 A

An aphanitic, dolerite sample with a black fresh surface and a dull, orange weathered surface. The fresh surface is black and smooth.

OBP5 D

A black dolerite sample with a black, rough weathered surface and a dull lustre. It seems coarse-grained (1 mm) on the weathered surface but is aphanitic on the inside. White, plagioclase laths are noted throughout the sample (10%).

OBP5 E

This dolerite has a brown weathered surface and an aphanitic, black fresh surface. Its lustre is dull and it has a smooth texture.

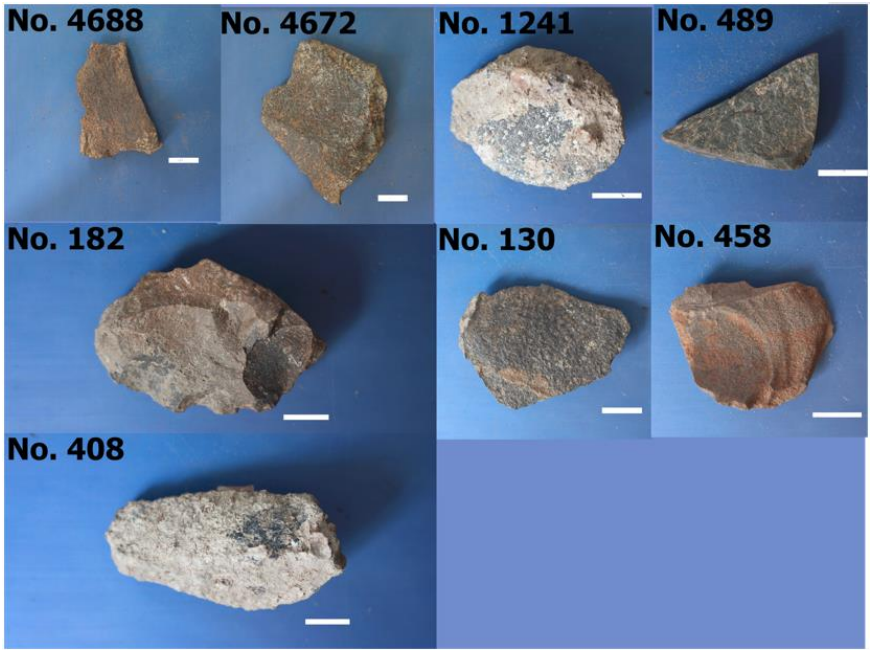

Figure A9: Dolerite lithics from OBP.

Quartz (Figure A10)

No. 493

A calcite coated, pink quartz pebble with a rough cortex.

No. 1290

A pink-white quartz sample with heavy calcite coating. The texture is smooth and it has a glassy lustre. A black fluid/oxidisation is noted in the sample.

MC1

A quartz conglomerate with rounded quartz pebbles (15%; 0.5-4.5 cm). The quartz pebbles have a purple and orange weathered surface, and a white fresh surface. The matrix of conglomerate is sandstone. It is coarse-grained (<2 mm) and has sub-rounded quartz grains (purple and white) in a white matrix (20%). Chlorite in association with the quartz grains is noted.

MC2

A conglomerate similar to MC1 with rounded quartz pebbles (10-15%; 1-7 cm) that have a purple and orange weathered surface and are white on the inside. The matrix is

coarse with purple and white sub-rounded to rounded quartz grains in a white matrix (20%). It has a brown, orange and purple weathered surface.

MC3

A conglomerate sampled at the contact between the Mogalakwena Formation and the Cleremont Formation (contact between a conglomerate and a pebbly sandstone). It has sub-rounded to rounded quartz pebbles and shows an upward coarsening trend throughout the sample. The sandstone section of the sample is coarse-grained (0.3-0.5 mm) with pink, sub-rounded grains in a white matrix (a band of black matrix is noted being 2-2.5 cm thick) (10%).

BPC1D

A rounded, red quartz pebble (4 cm) with a smooth texture and a dull lustre.

BPC1E

A rounded, white and pink quartz pebble (5 cm) with striations across the sample. It has a pitted and dull lustred cortex.

BB1

A conglomerate with rounded white quartz pebbles (1-3.5 cm) that have red, purple and white, smooth and dull cortices. The matrix is coarse-grained (1-10 mm) and the grains are sub-rounded.

OBP1

A conglomerate with red, rounded, and sub-angular quartz and quartzite pebbles (0.3-2 cm), found ex situ at the shelter. The quartzite pebbles have medium to coarse quartz grains. All pebbles have smooth, dull weathered surfaces. The matrix looks muddy (red-brown) and brittle. Could be a pebble lag.

OBP2

A monomictic conglomerate with sub-angular white quartz clasts (1-2.4 cm) (7%). There are black, muddy layers between clast beds which are 1 cm thick (banding/ mineralic cross-bedding). The matrix made of quartz grains (1 mm) in a white matrix (40%). Oxidation patches across the sample may be evidence of it being digenetic.

OBP3 A

A red euhedral quartz crystal (3cm).

OBP3 B

A sample of conglomerate grading into sandstone. The white quartz pebbles (0.5-1 cm) in the conglomerate pebble lag are rounded and cover 50% of pebble lag. They have an orange weathered surface and are in a sandstone matrix. This sandstone matrix is made of quartz grains (1 mm) in a white groundmass. Black oxidation patches noted throughout the sample.

OBP4 B

A rounded quartz pebble (4.5 cm) with an orange cortex and a grey fresh surface. It is smooth to touch and has a dull lustre.

OBP4 D

A milky white quartz vein (3.4 cm).

OBP5 C

A white quartz sample with orange weathering on its rounded cortex. It is smooth and has a dull lustre.

OBP5 F

A milky white quartz pebble sample with an orange weathered surface. The texture is smooth and the lustre is dull.

OBP6 C

A white quartz pebble (4 cm) with a smooth texture and a dull lustre. The weathered cortex is orange.

OBP6 D

A white quartz pebble (4 cm) with a smooth texture and a dull lustre. Its weathered surface is orange.

OBP6 E

A dull, red, quartz pebble (3.5 cm) with a smooth, orange cortex.

OBP9 A

A white, translucent quartz sample found at the top of a hill on the Zandrivier farm. It has a smooth texture and a dull lustre. The weathered surface is orange.

OBP9 B

A white, translucent quartz sample with an orange weathered surface. The sample is smooth and has a dull lustre.

OBP10 C

A smooth, rounded, red quartz pebble with a dull lustre.

OBP10 E

A pink-white quartz sample that is smooth to touch and has a dull lustre.

OBP10 F

A white quartz sample with a smooth, orange cortex that has a dull lustre.

Figure A10: Quartz lithics from OBP.

Chert (Figure A11)

No. 412

A cream white chert with calcite coating on one side. Elongate striations are noted across the sample.

Figure A11: A chert lithic (No. 412) from OBP.

7.1.2 Mwulu's Cave lithic and geological samples

Table A2: All lithic and geological samples from Mwulu's Cave, as well as their descriptions and rock types. The lithics were collected by either P. Tobias (1947) or P. de la Peña (2017).

White quartzite (Figure A12)

M1-I

A milky white quartzite with pink and yellow staining along grain boundaries. The weathered surface is brown and the texture of the sample is granular. The fine to medium sized grains (0.1-0.5 mm) are sub-angular and the smaller grains are white whereas the larger ones are more transparent and glassy. Grains are interlocking and no matrix is noted.

M2-D

A white quartzite with a granular texture and a shiny lustre. The weathered surface is an orange-stained white. It has sub-angular, medium (0.3-0.5 mm) quartz grains that are generally white but grey grains are also noted. These grains are interlocking and well-sorted in most parts of the sample. A white matrix is noted (10-15%).

No. 194

A clast-supported, white quartzite with a rough texture and a dull lustre. It has rounded to sub-rounded grains that are medium sized (0.2 mm). No matrix is noted.

No. 203

A coarse-grained (1-2 mm) milky white quartzite with a dull white weathered surface that is rough to touch. It has angular quartz crystals in a white matrix (15%).

No. 640

A coarse-grained (1-2 mm), clast-supported, white quartzite with a rough texture and a brownish-white, dull weathered surface. The quartz crystals are rounded to sub-rounded and the matrix is not clearly seen under the binocular microscope.

No. 676

A white quartzite with a rough texture and a dull lustre. The white (and a few grey) quartz grains are rounded to sub-rounded in a white matrix (5%).

No. 677

A coarse-grained (1-2 mm) pure white quartzite with a smooth texture and a glassy lustre. The sub-angular, glassy quartz crystals are annealed and no matrix is noted.

No. 1024

A pure white quartzite with a smooth texture and a glassy lustre. The quartz grained are medium sized (0.4 mm) and annealed. No matrix or pore spaces are noted.

No. 1021

A sample very similar to No. 1024. A pure white quartzite with medium to coarse (0.5-1.5 mm) quartz grains that are annealing. No matrix is noted.

No. 1410

A grey-white quartzite with a rough texture and a glassy lustre. The weathered surface is red. It has medium to coarse (0.5-2 mm) quartz grains that are sub-rounded and annealed. No matrix is noted.

No. 1699

A very fine-grained, crystalline, and white sample that is difficult to identify due to the heavy calcite coating. It does however have a smooth texture and a dull lustre (from small area under the coating).

No. 1815

A coarse-grained (1-2 mm) grey-white quartzite with a rough texture and a dull lustre. It has angular to sub-rounded quartz grains that are interlocking. No matrix is noted.

No. 1818

A white quartzite sample with a smooth texture and a glassy lustre. The grains are tightly interlocked and no matrix is noted. It is covered in calcite precipitate.

No. 2024

A coarse-grained (1-1.5 mm), white quartzite that is heavily covered with calcite precipitate, giving it a rough texture. From areas without the precipitate, rounded to sub-rounded grains are noted in about 10-15% matrix.

No. 2038

A grey-white quartzite sample with a rough texture and a glassy lustre. The quartz grains in this samples are medium to coarse-grained (0.4-1 mm). They are annealed, and no matrix is noted. Pore spaces are evident in 40% of the sample.

No. 2034

A coarse-grained (1-2 mm) greyish white quartzite that has a rough texture and a dull lustre. It is covered in precipitate quite heavily. The quartz grains are sub-angular and interlocking, and no matrix is noted.

PA-4

A highly weathered, grey-white sample with a rough texture and a dull lustre. Of the grains that can be seen, many seem to be fine to medium-grained (~0.2 mm).

PA-14

A grey-white quartzite with a rough texture and a dull lustre. The quartz grains are coarse (0.5-3 mm). They are also sub-angular and interlocking. No matrix is noted.

Outcrop 13

A white, coarse-grained (1-3 mm) quartzite sample with an orange weathered surface. The texture of the sample is gritty and rough with a dull lustre. The quartzite is friable. The crystals in this sample are sub-rounded and it is clast-supported.

Outcrop 16A

This quartzite sample is from the central fracture right above the opening of the cave. It is grey-white in colour and is heavily weathered. The grains are coarse (1 mm) and sub-angular. No matrix is noted. It has a gritty texture and a shiny lustre.

Outcrop 16E

A brittle, coarse-grained (1 mm) quartzite outcrop sample that has a green-grey and orange weathered surface. The grains in this sample are white and no matrix is noted.

Outcrop 19B

A grey-white, coarse-grained (1-1.5 mm) quartzite with a brittle texture and a dull lustre. No matrix is noted in this sample.

Outcrop 21A

A grey, coarse-grained (1 mm) quartzite with a gritty texture and a dull lustre. The quartz grains in this sample are sub-rounded and classify the rock as clast-supported. No matrix is noted.

G1

A coarse-grained (1-3 mm), light grey-white quartzite with a rough texture and a dull lustre. The quartz grains are sub-rounded and no matrix is noted.

G4

A coarse-grained (0.5-1 mm), grey-white quartzite with a rough texture and a shiny lustre. The grains in this sample are sub-rounded. No matrix is noted.

Figure A12: White quartzite lithics from Mwulu's Cave.

Black quartzite (Figure A13)

M1-J

A black quartzite with a rough, crystalline texture and a shiny lustre. It has angular to sub-angular black and white grains that are interlocking and no matrix is noted. These grains are medium to coarse-grained (0.5-1 mm).

M1-L

A medium to coarse-grained (0.2-2 mm) black quartzite with a granular texture and dull, orange weathered surface. It has sub-rounded to sub-angular grains that are interlocking (no matrix) and well-sorted. These are generally black but white and dark grey grains are also noted, as well as milky white larger grains (5 mm). A 0.5 mm thick quartz vein with orange staining runs through the sample.

No. 187

A coarse-grained (1-2 mm) black quartzite with a rough texture and a shiny lustre. It is clast-supported and has interlocking, sub-angular quartz grains. No matrix is noted.

No. 473

A coarse-grained (1-3 mm) black quartzite with a dull brownish-white weathered surface. The quartz grains are sub-rounded to sub-angular and the matrix consists of finer grains.

No. 799

A heavily weathered (also coated in calcite) black quartzite with a smooth texture and a dull lustre. The grains are coarse (<4 mm) and angular to sub-angular in shape. No matrix is noted.

No. 792

A black quartzite with a rough texture and a shiny lustre. Its weathered surface is orange. The medium to coarse (0.5-2 mm) quartz grains are sub-rounded to sub-angular and no matrix is noted.

No. 794

A black quartzite that has a rough and dull (heavily-) weathered surface that is orange. It has medium to coarse (0.5-4 mm), black and grey, sub-rounded quartz grains. No matrix is noted.

No. 684

A coarse-grained (1-5 mm), black quartzite with a rough texture and a shiny lustre (under calcite coating). The quartz grains are sub-rounded to sub-angular and they are annealed. No matrix is noted.

No. 672

A black quartzite with a rough texture and shiny lustre. It has medium to coarse (0.5-1 mm) quartz grains that are sub-rounded to sub-angular and are interlocked with each other. No matrix is noted.

No. 837

A glassy, smooth-textured, black quartzite with interlocking, medium to coarse (0.5-4 mm), sub-angular quartz grains (black and grey). No matrix is noted

No. 836

A black quartzite with a smooth texture and a glassy lustre. It has black, grey and white (in decreasing proportion) rounded to sub-rounded quartz grains. These are medium to coarse (0.5-2 mm). No matrix is noted.

Outcrop 8A

A black, medium to coarse-grained (0.6-2 mm) sample with no visible matrix or layering. It is crystalline and covered in red sand.

Outcrop 16D

A coarse-grained (1-2 mm) quartzite that is black in colour. It is rough to touch and has a dull lustre. The grains are sub-rounded and no matrix is noted.

Outcrop 18A

A dark grey-black quartzite with coarse (0.6-1 mm), rounded quartz grains. The sample is clast-supported and rough to touch. The lustre is dull. No matrix is noted.

G2A

A black quartzite that is rough to touch and has a dull lustre. The grains are coarse (1-2 mm) and sub-angular. No matrix is noted.

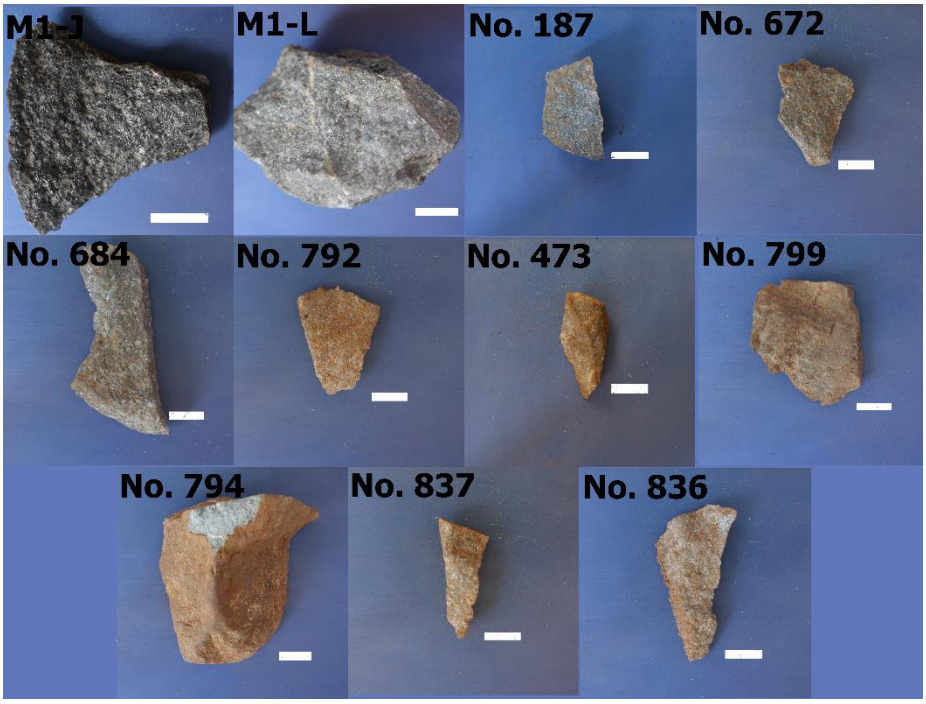

Figure A13: Black quartzite lithics from Mwulu's Cave

Quartzite with pore spaces (Figure A14)

M1-A

A white quartzite with a rough texture and a glassy lustre. It has a cream white weathered surface. The grains are medium sized (0.5 mm) and they interlock and anneal in some areas of the sample. These grains are milky white (rounded), while others are glassy (interlocking and annealing; making sample look like porridge under the binocular microscope). The sample has pore spaces (15%) the size of the grains throughout it and no matrix is noted.

M1-C

A coarse-grained (0.6-2.4 mm), white quartzite with a rough texture and a glassy lustre. Green chlorite clusters (5%), and pore spaces (5%) are noted throughout sample. The quartz grains in this sample are rounded and formed in a white matrix (30%).

M2-A

A coarse-grained (1-2.5 mm) white quartzite with a rough texture and shiny lustre. The weathered surface is orange. Generally, it has rounded quartz grains (some as large as 0.7 cm). It also has some areas with quartz grains that are annealed. The sample is covered in pores paces (30%). Orange staining is noted along grain boundaries and no matrix is evident.

M3-A

A very coarse-grained (1-3 mm) milky white quartzite with a smooth texture and glassy lustre. It has a cream white weathered surface with some orange staining. The grains in this sample are mostly milky white while some grey grains are also noted (10%). All these grains are sub-rounded to sub-angular and there is a high degree of annealing on half of the rock (other half has about 15% matrix). Pore spaces are noted throughout the sample (15%) (some pore spaces look filled by sand).

M3-C

A very fine (cannot see individual sand grain boundaries) red quartzite with a smooth texture and a shiny lustre. It has a pinkish-orange weathered surface and pore spaces cover 15-20% of the sample. No matrix is noted.

No. 1679

A medium-grained (0.2-0.3 mm), white quartzite sample with a rough texture and a glassy lustre. It has a brown weathered surface. The quartz grains are sub-rounded and interlocking. There are pore spaces throughout the sample (10%) and no matrix is noted.

No. 2118

A white quartzite with a smooth texture and glassy lustre. The quartz crystals in this sample are medium to coarse-grained (0.3-0.6 mm), and annealed. There are pore spaces the size of the grains throughout the sample. No matrix is noted.

No. 2134

A medium-grained (0.3 mm), white quartzite with a rough texture and a glassy lustre. The quartz crystals in this sample are interlocking. Pore spaces are noted (same shape and size as grains) throughout the sample (30%).

No. 2135

A grey-white quartzite with a rough texture and a dull lustre. Its weathered surface is cream white and, rough and dull. It has medium to coarse (0.3-1 mm) quartz grains that are interlocking. 20% of the sample is covered in pore spaces.

No. 1826

A coarse-grained (1-2 mm), white quartzite with a rough texture and shiny lustre. Its quartz grains are rounded and annealed. 40% of the sample is covered in pore spaces and no matrix is noted.

No. 2080

A medium-grained (0.5 mm), white quartzite sample with a rough texture and a glassy lustre. The quartz grains in this sample are sub-rounded to sub-angular, and are interlocked. 30% of the samples is characterised by pore spaces and there is a degree of foliation in the alignment of the quartz grains.

No. 2070

A pure white, coarse-grained (1-2 mm) quartzite with a rough texture and a shiny lustre. The quartz grains in this sample are sub-rounded to sub-angular and are interlocking. pore spaces are noted throughout the sample (5%).

PA-6

A coarse-grained (1-1.5 mm), grey-white quartzite with a smooth texture and a glassy lustre. It has pore spaces covering about 20% of its surface. The quartzite grains are sub-rounded and interlocking. No matrix is noted.

PA-7

A grey-white, coarse-grained (1-1.5 mm) quartzite sample with a rough texture and a dull lustre. The quartz grains are sub-rounded and interlocking. There are pore spaces smaller than the grains (0.5 mm) throughout the sample (10%). No matrix is noted.

PA-9

A white quartzite with a smooth texture and a glassy lustre. Pore spaces are noted throughout the sample (5%). The quartzite grains are strongly annealed and no matrix is noted.

PA-15

A medium-grained (0.5 mm), grey-white quartzite with a rough texture and dull lustre. Pore spaces are noted throughout the sample (5%). The quartz grains are sub-angular and interlocking.

PA-16

A pure white quartzite with a rough texture and glassy lustre. The quartz grains are sub-rounded and interlocking, and pore spaces are noted throughout the sample (7%). No matrix is noted.

M1-B

A coarse-grained (1-4 mm), black quartzite with a smooth texture and a glassy lustre. It has sub-angular grains that are annealed and pore spaces are noted throughout the sample (5%). No matrix is noted.

M1-H

A coarse-grained (0.5-1 mm), black quartzite with a smooth texture and a glassy lustre. Some grains are glassy (quartz) while others are clayey (5%). The quartz crystals are annealed, and no matrix is noted. Pore spaces are seen throughout the sample (5%).

M1-M

A coarse-grained (0.5-2.5 mm) black quartzite with a smooth texture and a glassy lustre. The weathered surface of this sample is dull and has red staining. The quartz grains are mostly annealed, while some are just interlocking. A clayey grain is noted in 20% of the sample whereas pore spaces cover 5% of it. No matrix is noted.

PA-1

A black quartzite with a rough texture and a glassy lustre. The sample has pore spaces throughout it (10%) and no matrix is noted. It is medium to coarse-grained (0.5-1.5 mm) and made of interlocking, sub-angular quartz grains.

No. 2130

A black quartzite with a rough texture and glassy lustre. There is some calcite coating on the sample. Its quartz crystals are coarse-grained (0.5-2 mm), angular and interlocking (no matrix). Pore spaces of the same size as the grains are noted throughout the sample (10%). Rounded, white grains (same size as quartz grains) whose surfaces are easily scratched off are also noted throughout the sample (2%).

No. 2133

A coarse-grained (1 mm) black quartzite with a smooth texture and a shiny lustre. Pore spaces are noted throughout the sample (5-10%) and the quartz grains (black and grey) are annealed. No matrix is noted.

Figure A14: Quartzite lithics with pore spaces from Mwulu's Cave.

Quartzite with plane beds (Figure A15)

No. 673

A plane bedded quartzite with a rough texture and a shiny lustre. The white beds are around 2 mm thick and the grey beds 0.8mm thick. The quartz grains are medium sized (0.5 mm) and have a sub-rounded shape. Grains are interlocking and no matrix is noted.

Outcrop 17

A medium to coarse-grained (0.5-2 mm) quartzite with white and dark grey banding. The grains are sub-rounded and interlocking. No matrix is noted. The sample is rough (almost gritty) and has a shiny lustre.

Outcrop G2B

A white and grey banded quartzite with a rough texture and a dull lustre. The quartz grains are coarse (1-4 mm), and sub-rounded to sub-angular. No matrix is noted.

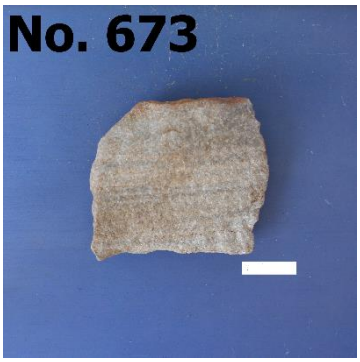

Figure A15: A plane bedded quartzite lithic (No. 673) from Mwulu's Cave.

Shale (Figure A16)

M1-D

A very fine-grained (can’t see individual grains), dark grey shale with a smooth texture and a dull lustre.

M3-B

A very fine-grained (<0.2 mm) grey shale with a dull weathered surface and a rough, crystalline fresh surface (shiny lustre). Grains can only be identified by reflective surfaces under the binocular microscope but their boundaries cannot be seen. Most of these grains are black but a few white ones are noted.

M3-D

A very fine-grained (cannot see individual grains), dark grey shale with a smooth texture and a dull lustre.

M3-E

A very fine-grained (cannot see individual grains), black shale with a smooth texture and a dull lustre. It has pore spaces (0.6 mm) dispersed across the sample (10%).

M3-F

A very fine-grained (cannot see individual grains), dark brown to black sample with a smooth texture and dull lustre. Its fresh surface seems red and crystalline and its weathered surface seems brown with black staining under the binocular microscope.

No. 1240

A very fine-grained (cannot see individual grains), black shale with a smooth texture and a dull lustre. The weathered surface is dark brown.

No. 2026

A very fine-grained (cannot see individual grains), dark grey shale with a smooth texture and a dull lustre.

PA-3

A very fine-grained (cannot see individual grains) grey-black shale with a smooth texture and a dull lustre.

PA-12

A very fine-grained (cannot see individual grains) black shale sample with a smooth texture and a dull lustre.

PA-13

A fine-grained, red-brown shale that is smooth to touch and has a dull lustre. A lighter red band is noted below quartz fluid inclusions.

Outcrop 1

A meta-sedimentary rock with a dull, red-brown weathered surface. This sample is layered with a black fluid crystallisation found through and along the meta-sedimentary bed. The black layers are 0.7-1 cm thick and have a smooth, shiny lustre, and no crystals. The meta-sedimentary layers are medium-grained (<0.5 mm).

Outcrop 2A

A green-grey, very fine-grained shale with a smooth texture and a dull lustre.

Outcrop 2B

A very fine-grained, dark grey shale with a smooth texture and a dull lustre.

Outcrop 2C

A medium to coarse-grained (0.3-1.5 cm) breccia with shale and dolomite sub-angular clasts in a red muddy matrix. The clasts are randomly orientated

Outcrop 3C

A dark grey shale that has a very fine-grained, smooth texture and a dull lustre. It is layered within Malmani dolomites that have stromatolites on them.

Outcrop 4A

A very fine-grained, black shale that is smooth to touch and has a dull lustre. No visible layers are noted.

Outcrop 4B

A very fine-grained, dark grey shale with no noted bedding. It has a smooth texture and a dull lustre.

Outcrop 6

A dark grey shale from the Cave of Hearths. It has very fine grains, smooth and has a dull lustre.

Outcrop 8B

A very fine-grained, green-grey sample that looks red on the inside. No bedding is noted. It is smooth to touch and has a dull lustre.

Outcrop 9

A very fine-grained, green-grey shale. It has no bedding, and it has a smooth texture and dull lustre.

Outcrop 10

A very fine-grained, purple-red meta-sedimentary sample with some grey patches throughout the sample. The sample is smooth to touch and has a dull texture.

Outcrop 12

A very fine-grained, grey shale with an orange to red weathered surface. There is fine bedding on the edges of the sample and mica (light gold) is noted along these bedding planes.

Outcrop 14A

A sample that looks like metamorphosed shale. It is black in some areas and light green-grey in others. This meta-sedimentary sample has very fine grains (not visible with the naked eye) and thin bedding is noted on the edge of the sample.

Outcrop 14B

A light grey, very fine-grained shale with a smooth texture and a dull lustre.

Outcrop 18B

A light green-grey shale with a very fine-grained texture. It has a smooth, orange and grey weathered surface, and a dull lustre. No bedding is noted.

G3

A very fine-grained, grey (4 mm) and red-grey (6 mm) banded shale with shiny mica along the bedding planes. It is smooth to touch and has a dull lustre.

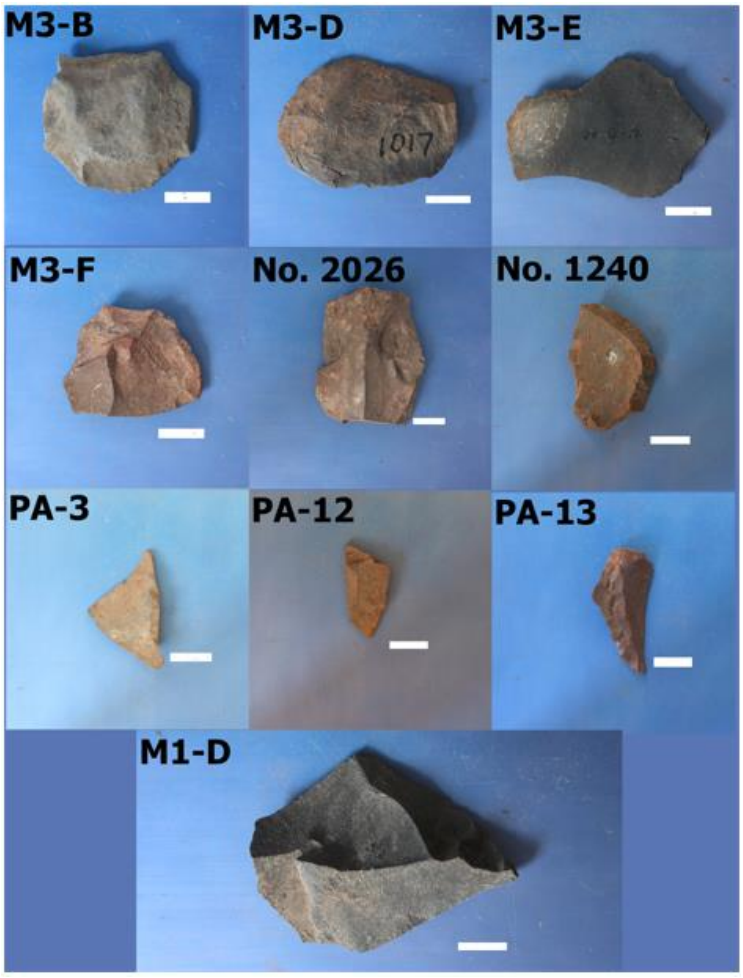

Figure A16: Shale lithics from Mwulu's Cave.

White Quartz (Figure A17)

M1-F

A white quartz sample with a smooth texture and glassy lustre. There is orange staining in the cracks of the sample.

No. 195

A white quartz crystal with a smooth texture and a glassy lustre.

PA-2

A white quartz sample with a smooth texture and a dull lustre.

No. 1839

A white quartz sample with a smooth texture and a glassy lustre. It is covered in calcite precipitate in most areas.

No. 2132

A white quartz sample that is smooth to touch and has a glassy lustre. Orange staining is noted along cracks.

No. 1835

A milky quartz sample with a smooth texture and a glassy lustre. Cracking is noted along the length of the sample.

PA-5

A white quartz sample with orange staining. The texture is rough and it has a dull lustre.

PA-8

A milky white quartz sample with a smooth texture and a dull lustre. Pits and cracks are noted throughout the sample.

Outcrop 16B

A light grey-white silica vein sample from the wall of the cave. It has a smooth texture and a glassy lustre.

Outcrop 19A

A white quartz vein with a smooth texture and dull lustre.

Outcrop 20

A white and red quartz vein with a smooth texture and a glassy lustre.

Outcrop 21B

A dull, white, quartz vein with a dull lustre and a smooth texture.

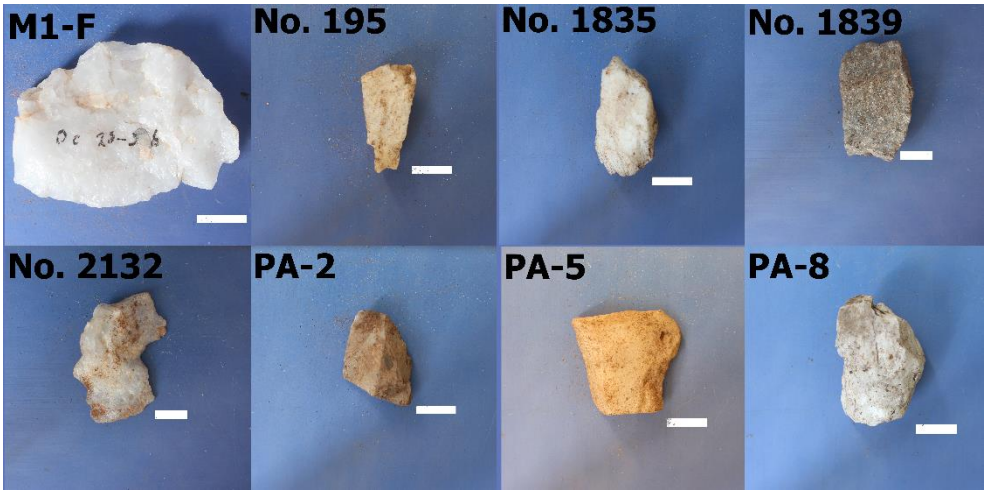

Figure A17: White quartz lithics from Mwulu's Cave.

Translucent Quartz (Figure A18)

No. 2073

A translucent, white quartz sample with a smooth texture and a dull lustre.

PA-10

White translucent quartz sample with a smooth texture and a glassy lustre.

Outcrop 16F

A clear quartz sample with orange staining.

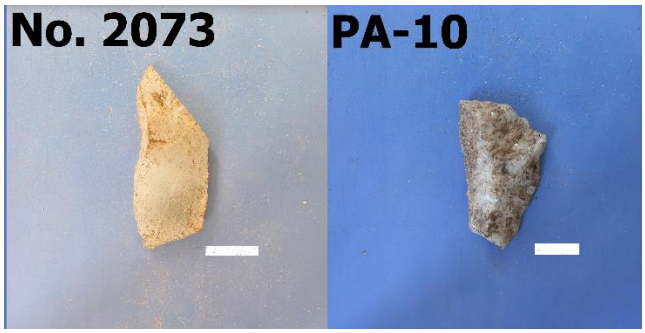

Figure 5.18: Translucent/clear quartz lithics from Mwulu's Cave.

Chert (Figure A19)

M1-K

A very fine-grained (cannot see individual grains) and banded chert that is smooth to touch and has a dull, powdery lustre. Half of it is dark grey and the other half is light grey.

PALO49

A grey chert with a rough texture and a dull lustre. It is heavily coated with calcite.

No. 674

A very fine-grained (no visible grains) chert with a smooth texture and a dull lustre. It has dark grey (4 mm thick) and light grey (8 mm thick) banding.

Outcrop 3B

A dark grey, chert sample with a smooth texture and a dull lustre.

Outcrop 4C

A very fine-grained, grey chert with what looks like ooids in single layer. This sample is smooth to touch and has a dull lustre.

Outcrop 11

A conglomerate with sub-rounded and angular, grey chert clasts (0.5-2.3 cm) in a sandy matrix composed of sandstone. The sample has a red weathered surface and is rough to touch. Its lustre is dull.

Outcrop 16C

A milky, grey-white chert with a smooth, fine silt grained texture, and a dull lustre. This sample was also collected from the wall of the cave.

Figure A19: Chert lithics from Mwulu's Cave.

Altered samples (Figure A20)

M1-E

A red-brown, altered rock/pyroclastic pumice that is rough to touch, has a dull lustre, and feels very light weight. It is very porous with a few pore spaces (~15) noted on its surface (1 mm). Some brown staining is noted throughout the sample.

M1-G

A yellow, altered rock/pyroclastic pumice that is gritty and brittle to touch and has a dull lustre. It is also light weight although no pore spaces are noted on its surface. A brown coating is noted with black spotting (<1 mm) across the surface.

M2-B

A sample very similar to M1-E. It is red-brown, fine-grained, porous, and light weight altered rock/pumice with a few elongate pore spaces throughout it. It is gritty to touch and has a dull lustre.

M2-C

A brittle, light green-grey altered rock that scratches easily. It has a smooth, fine-grained texture and a dull lustre. This sample is also light weight, although a little heavier that the other mentioned altered samples.

PA-11

A very weathered and light weight sample that may be an altered meta-sedimentary rock. It has an orange-brown, rough, and dull weathered surface.

Figure A20: Altered lithics from Mwulu's Cave.

APPENDIX B

8.2 Portable X-ray Fluorescence Results Spreadsheets

Table B1: PXRF spreadsheet of Olieboomspoort Rock Shelter (OBP) lithic and outcrop samples. Concentrations of major elements Mg, Al, Si, P, S, K, Ca, Ti, and Fe are measured in weight percentage while the rest of the elements' concentrations are measured in ppm.

Table B2: PXRF spreadsheet of Mwulu's Cave lithic and outcrop samples. Concentrations of major elements Mg, Al, Si, P, S, K, Ca, Ti, and Fe are measured in weight percentage while the rest of the elements' concentrations are measured in ppm.

APPENDIX C

8.3 Detailed thin section descriptions

8.3.1 OBP detailed thin section descriptions

Quartzite

No. 486

A quartzite with quartz grains (90%) in a very fine microcrystalline matrix (5%). The quartz grains are angular to sub-rounded and have convex-concave crystal boundaries. Under XPL the quartz grains have low light and dark grey interference colours. They become extinct every 90˚ (only 25% have undulose extinction). The lesser minerals in the sample are the following: muscovite minerals with similar colour as quartz in PPL but have bright orange interference colours and uniform extinction in XPL (3%); blue laths that have light blue, orange, white, purple interference colours in XPL (1%); and purple minerals that are isotropic under XPL (1%). This rock is moderately sorted and clast supported. Most of the grains are interlocking. About 40% quartz syntaxial cement is noted and black dissolution is present in association with the matrix. Deformation lamellae (Bohm lamellae) are noted in the quartz grains (30-40%).

No. 3478

This quartzite is composed of quartz grains (90%). The quartz grains have a sub-rounded shape with iron oxide orange staining on the grain boundaries (concave-convex). They have a low grey interference colour whereas the iron oxide staining is a bright pink-orange. Under XPL some grains show undulose extinction (20%) whereas the rest show uniform extinction. This quartzite is well-sorted. These minerals are tightly interlocking and two bands of finer quartz grains are noted. Pitting is evident in most grains although no deformation lamellae are noted on the grains. Instead, quartz syntaxial cement is present outside of some grain boundaries (40-50%). An opaque fluid is scattered throughout the sample on the quartz grains, particularly at their boundaries.

CMF1

This quartzite has yellow-white quartz grains that are sub-rounded to sub-angular (90%). Opaque minerals (5%; isotropic in XPL) are also noted in the black matrix (5%). The interference colours of the quartz grains are a first-order light grey and dark grey. It is noted that the quartz grains in the sample generally have a uniform extinction although undulose extinction is also seen (20-30%). This quartzite is well-sorted and the grains are interlocking although some of the grains are annealed. About 45% of the quartz grains have quartz

synatxial cement outside of their original grain boundaries. Black dissolution is noted throughout the samples especially along grain boundaries. About the 25% of the grains are pitted and have embayments filled with matrix material. The quartz grains have very few deformation lamellae.

Shale

No. 164

This is a brown, cryptocrystalline shale. It has chlorite occurring in clusters throughout the sample (20%), as well as rounded opaque minerals (10%) that are chloritised. The chlorite has a low birefringence and a dark green-brown anomalous interference colour In XPL. The matrix is a yellow-brown and dark green colour under crossed polars. The birefringence is low and the yellow minerals show uniform extinction.

YRS1-D

A green-brown, cryptocrystalline shale with chlorite minerals in random clusters and disseminated throughout the sample (25%). This chlorite is a dull blue-green-brown interference colour under XPL. Other minerals include irregularly shaped opaque grains (15%), liquid inclusions (10%); and orange laths (2%) in a green-brown matrix (48%). The orange laths have a bright orange interference colour and a uniform extinction angle under XPL.

OBP 10A

A greenish grey shale sample. 20% of the sample is covered by sub-rounded to rounded opaque minerals that are isotropic under XPL. The sample is predominantly composed of a cryptocrystalline matrix (80%). Darker green-grey cloudy patches are noted towards the bottom right corner of the image. These are also isotropic under XPL. Towards the left edge of the image irregular opaque masses that look like lichens are visible.

Sandstone

No. 2402

This sandstone (sub-litharenite) is made of detrital quartz grains of different sizes (60%), lithic fragments (20%) muscovite (10%), and augite (2%) in an opaque matrix (8%). The quartz grains are angular to sub-angular. They have a low grey to dark grey interference colour. Under XPL, it is noted that about 40% of the quartz grains undergo undulose extinction while the rest show uniform extinction. Other minerals noted in

this sample include microcrystalline lithic fragments that are multi-coloured with no general extinction in XPL. The irregularly shaped muscovite minerals (visible cleavage and colourless) have bright orange, pink, green, and blue interference colours in XPL. The augite in this sandstone has an obvious cleavage and is green in PPL. Under XPL it shows bright third-order interference colours (blue and green). Lastly, another irregularly shaped grain similar to quartz is noted although it is isotropic in XPL. The matrix is isotropic in XPL and the sample is poorly sorted. The quartz grains have many fractures and about 20% of them have deformation lamellae.

No. 1194

This rock is a green-brown greywacke (sandstone). It is composed of white, angular to sub-rounded, detrital quartz grains and quartz phenoclasts (80%) in a green-brown matrix (20%). They have first-order grey and white interference colours and uniform extinction although a few of the grains show undulose extinction. Rounded quartz grains are also noted. A large, dark brown lithic fragment that is rounded and has with white plagioclase laths is present in the sample. A few more similar grains without the laths (3%), as well as opaque minerals (2%), are also noted. The lithic fragment shows undulose extinction and its laths are multi-coloured but dull under XPL. Lastly, the opaque grains are isotropic and their rims are a dull brown under XPL. The sample is poorly sorted and the minerals are disseminated throughout it. The quartz grains in this sample show a degree of pitting and fracturing (40%), especially the larger grains.

OBP 7

OBP 7 is an arkose with 60% of its composition being of sub-rounded and irregularly shaped quartz grains. The remaining 40% of the rock consists of perthitic alkali feldspar. The quartz grains are brown-white in colour. Under XPL, they go extinct every 90˚ and have a low grey interference colour. The alkali feldspars are altered and are a cloudy brown in PPL. Under XPL. They have low white and brown interference colours. Overall, the arkose is poorly sorted and the alkali feldspar grains are older than the quartz grains, all of which are interlocking. The quartz grains also have black dissolution on some of their grain boundaries and orange fluid running over them. The orange fluid remains orange under XPL. Most grains look pitted (90%) and some have fractures (40-50%) running through them.

OBP 8A

The mineralogy of this sandstone (greywacke) includes quartz (55%), muscovite (20%), and opaque minerals (5%) in a microcrystalline matrix (20%). The quartz grains are light yellow-white in colour and have an angular to sub-angular (some irregular) shape. Under XPL, these quartz grains have a first-order grey interference colour and a uniform extinction. Undulose extinction is noted (55%). The matrix is multi-coloured in XPL. Muscovite grains have bright orange, blue, green, and pink interference colours and an extinction parallel to cleavage under XPL. The opaque minerals are isotropic under XPL. The grains are

poorly to moderately sorted and a few concave-convex relationships are evident (25%). There are two foliations (bands) of opaque minerals towards the top of the image. A few deformation lamellae are noted in the quartz grains (25%).

Dolerite

No. 458

In PPL, the fine-grained andesite has a black matrix and white plagioclase feldspar laths (80%). In XPL, the plagioclase laths are white and grey (first-order interference colours) although they are too fine for twinning to be noted. Aphanitic brown and yellow-brown minerals are noted surrounding the plagioclase laths (10%). Under XPL these are blue, yellow and green suggesting augite and hornblende mineralogy. The plagioclase laths are randomly oriented in the matrix.

OBP 4G

This dolerite is composed of white plagioclase laths (80%), white euhedral phenocrysts (5%), and augite (15%). The plagioclase laths are euhedral and have a low birefringence under XPL. It is difficult to see their multiple twinning under XPL due to their size and altered nature. The phenocrysts are a low grey and white in XPL whereas the augite looks orange-yellow (third-order interference colour). These minerals are randomly orientated in the matrix (made of the same minerals). The phenocrysts are highly altered and have a brown mineralisation along their grain boundaries.

8.3.2 Mwulu's Cave detailed thin section descriptions

Quartzite

No. 640

No. 640 is a quartzite made of rounded to sub-rounded quartz grains (90%) in a dark brown matrix (10%). The quartz grains have first-order grey interference colours and the matrix is multi-coloured under XPL. Most quartz grains undergo undulose extinction (80%) although some undergo uniform extinction. This quartzite is very well-sorted and clast-supported. Most of the grains are interlocking and have convex-concave grain boundary relationships. Under XPL, it is evident that many grains (85%) have quartz

syntaxial overgrowths. The quartz grains are highly pitted and fractured although a no deformation lamellae are noted.

No. 1021

This sample is a porous (30%) quartzite predominantly composed of coarse quartz. The grains have first-order grey interference colours and some of them have blue staining under XPL. Many of the grains undergo undulose extinction (45%) while the rest show uniform extinction. The grains are of irregular shapes and they are annealed. These grains have no syntaxial cement. They are pitted and highly fractured but no deformation lamellae are noted.

M1-J

A quartzite with quartz grains (90%) in a dark, microcrystalline matrix (10%; multi-coloured in XPL). The quartz grains are a light yellow-white in PPL and a first-order grey in XPL. About 65% of the grains show undulose extinction and the rest uniform. The quartz grains vary in size, ranging from fine to coarse (a band of coarser grains with finer grains on either side). For that reason, this quartzite is poorly sorted. The smaller quartz grains are interlocking and some have concave-convex boundary relationships (45%). Pitting is noted (30%) and about 35% of the quartz grains have quartz syntaxial cement.

Outcrop 16A

This quartzite is composed of quartz grains (95%) in a dark microcrystalline matrix (multi-coloured under XPL; 5%). The quartz grains are rounded, sub-rounded, and sub-angular. Under XPL, the quartz grains have a first-order interference colours (grey). About 75% of the grains show undulose extinction. This quartzite has moderate to well sorting and most of the grains are interlocking with concave-convex boundary relationships. A band of finer quartz grains runs through the rock. The quartz grains are bordered by a thin film of orange mineralisation (iron oxide). Quartz syntaxial cement is visible outside of some of the quartz grain boundaries (30-40%). Moderate pitting and fracturing is noted throughout the sample, as well as a large crack. Deformation lamellae are absent.

Outcrop G2A

A quartzite with quartz grains (90%) in a dark, microcrystalline matrix (10%). The quartz grains are light yellow-white in colour and have an angular to sub-angular shape. Under XPL, the grains have light grey and dark grey first-order interference colours. About 70% of the grains have undulose extinction. The matrix is dark and multi-coloured under XPL. Overall, this quartzite is poorly sorted. The grains are pitted and some have embayments incorporating the same material as the matrix (5%). No fracturing is noted.

Outcrop G2B

A quartzite with large quartz grains (65%) and finer, rounded grains (35%). The larger quartz grains are vary in shape (angular to sub-rounded). Under XPL, all the quartz grains show a first-order light and dark grey interference colour. Many (70%) of the grains show undulose extinction and rest have a uniform extinction. This quartzite is poorly sorted and the different quartz types are concentrated in different parts of the rock. The grains are highly interlocked and annealed. A low degree of quartz syntaxial cement is noted (15%). The larger quartz grains are more pitted and fractured than the grains and no deformation lamellae are noted.

Shale

M3-E

A cryptocrystalline, green-brown shale. Opaque minerals are scattered throughout the sample (20%). These are isotropic under XPL. The whole rock is multi-coloured but very dark under XPL. Pore spaces are evident throughout the sample (10%).

Outcrop 4A

This is a grey, very fine-grained shale. There are opaque minerals with white rims scattered across the sample (5%). A single orange mineral that is isotropic under XPL is noted in this sample. The shale has a foliated section running across it. The grains along this foliation are white and grey. They also show oblique extinction under XPL.

Sandstone

M3-B

A fine-grained, brown sandstone composed of quartz (60%), biotite (30%), and multi-coloured minerals (10%). The detrital quartz grains are sub-rounded to sub-angular. These are a low white and grey under XPL. Undulose extinction is noted (10%) although most quartz grains show uniform extinction. Yellow-brown biotite is identified through its cleavage and second-order yellow interference colour under XPL. It also has an extinction pattern that is parallel to this cleavage. The multi-coloured (blue, green, pink) minerals are too fine to identify. This sandstone is well-sorted although large areas of the sample are pore spaces (20% of the rock). The biotite and multi-coloured minerals occupy the spaces between the quartz grains.
