PALAEONTOLOGICAL IMPACT SCREENING REPORT

PROPOSED CLOCOLAN SOLID WASTE DISPOSAL FACILITY

On the Farm: Ferndale 349 of the Setsoto Municipality within the Thabo Mofutsanyane District Municipality in the Free State Province of South Africa

Developer: Setsoto Municipality

22 March 2012

EXECUTIVE SUMMARY

The development of a Solid Waste Disposal Facility near Clocolan in the Eastern Free State is an initiative of Setsoto Municipality. The purpose of this Palaeontological Impact Assessment is to identify exposed and potential palaeontological heritage on the site of the proposed development, to assess the impact the development may have on this resource, and to make recommendations as to how this impact might be mitigated.

The Setsoto Municipality plans to develop a solid waste disposal facility located to the west of Clocolan and Hlohlowane on the farm Ferndale 349. The area is next to the R703 tar road leading from Clocolan to Excelsior. The facility footprint is approximately 3 ha.

A basic assessment of the topography and geology of the area was made by using appropriate geological (1:250 000) maps in conjunction with Google Earth. A review of the literature on the geological formations exposed at surface in the development site and the fossils that have been associated with these geological strata was undertaken.

The proposed Clocolan solid waste disposal site is underlain by the Triassic Molteno Formation that consists of coarse-grained grey sandstone and dark grey mudstone. Soils are derived from the underlying rock and are generally deep and relatively high in fertility.

The Molteno Formation has a high palaeontological sensitivity rating. Through adequate monitoring and mitigation measures during excavations within the bedrock, the impact severity can be lowered to beneficial. The exposure and subsequent reporting of fossils (that would otherwise have remained undiscovered) will be a beneficial palaeontological impact.

It is recommended that the resident ECO be trained by a professional palaeontologist in the recognition of fossil material. If fossil material is later discovered it must be appropriately protected and the discovery reported to a palaeontologist for the removal thereof.

That all earth-moving activities within the bedrock with a potential impact on the Adelaide Subgroup be monitored by a palaeontologist. That a monitoring report be submitted to SAHRA after the completion of the earth works phase.

1. INTRODUCTION

The development of a Solid Waste Disposal Facility near Clocolan in the Eastern Free State is an initiative of Setsoto Municipality. The purpose of this Palaeontological Impact Assessment is to identify exposed and potential palaeontological heritage on the site of the proposed development, to assess the impact the development may have on this resource, and to make recommendations as to how this impact might be mitigated.

1.1. Legal Requirements

This report forms part of the Scoping and Environmental Impact Assessment for the CLOCOLAN WASTE DISPOSAL SITE and complies with the requirements for the South African National Heritage Resource Act No 25 of 1999. In accordance with Section 38 (Heritage Resources Management), a Palaeontological Impact Assessment is required to assess any potential impacts to palaeontological heritage within the development footprint of the Clocolan Solid Waste Disposal site.

Categories of heritage resources recognised as part of the National Estate in Section 3 of the Heritage Resources Act, and which therefore fall under its protection, include:

- geological sites of scientific or cultural importance;
- objects recovered from the soil or waters of South Africa, including archaeological and palaeontological objects and material, meteorites and rare geological specimens; and
- objects with the potential to yield information that will contribute to an understanding of South Africa's natural or cultural heritage.

2. AIMS AND METHODS

After discussions with LHL Engineers a request for a Palaeontological Impact Screening was received. Following the *"SAHRA APM Guidelines: Minimum Standards for the Archaeological & Palaeontological Components of Impact Assessment Reports"* the aims of the Palaeontological Impact Screening were:

- identifying exposed and subsurface rock formations that are considered to be palaeontologically significant;
- assessing the level of palaeontological significance of these formations;
- commenting on the impact of the development on these exposed and/or potential fossil resources;
- making recommendations as to how the developer should conserve or mitigate damage to these resources.

A basic assessment of the topography and geology of the area was made by using appropriate geological (1:250 000) maps in conjunction with Google Earth. The only limitation on this methodology is the scale of mapping, which restricts comparison of the geology to the 1:250 000 scale. This restriction only applies in areas where major changes in the geological character of the area occur over very short distances or on the geological transformation zones.

A review of the literature on the geological formations exposed at surface in the development site and the fossils that have been associated with these geological strata was undertaken.

3. PROPOSED DEVELOPMENT DESCRIPTION

The Setsoto Municipality plans to develop a solid waste disposal facility located to the west of Clocolan and Hlohlowane on the farm Ferndale 349. The area is next to the R703 tar road leading

from Clocolan to Excelsior. The proposed facility general GPS co-ordinates are 28°54'30.15" S and 27°32'20.57" E (Figure 2.1). The facility footprint is approximately 3 ha.

The solid waste disposal facility will be constructed with accompanying infrastructure to supply in the demand for waste disposal for the next 10 years. These waste cells will be approximately 35m wide, 180m long and 2m deep.

Waste will be dumped in the cells and compacted until the waste reaches ground level when it will be covered. When the cells are full the actual land building will start. The waste will be dumped, compacted and covered in 2m layers until an eventual height of 13 m is reached.

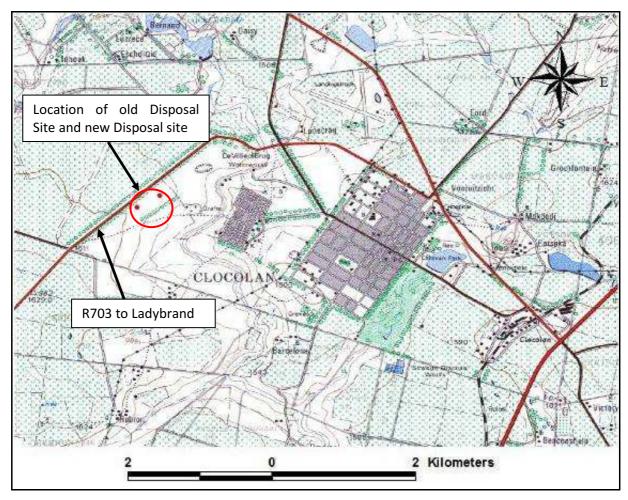

Figure 3.1 Locality Map

4. GEOLOGY OF THE AREA

The geology around development area is underlain by the Molteno Formation (Trm) of the Karoo Supergroup as illustrated in Figure 4.1.

4.1. The Molteno Formation

The proposed development site is underlain by the Triassic Molteno Formation that consists of coarse-grained grey sandstone and dark grey mudstone. Soils are derived from the underlying rock and are generally deep and relatively high in fertility.

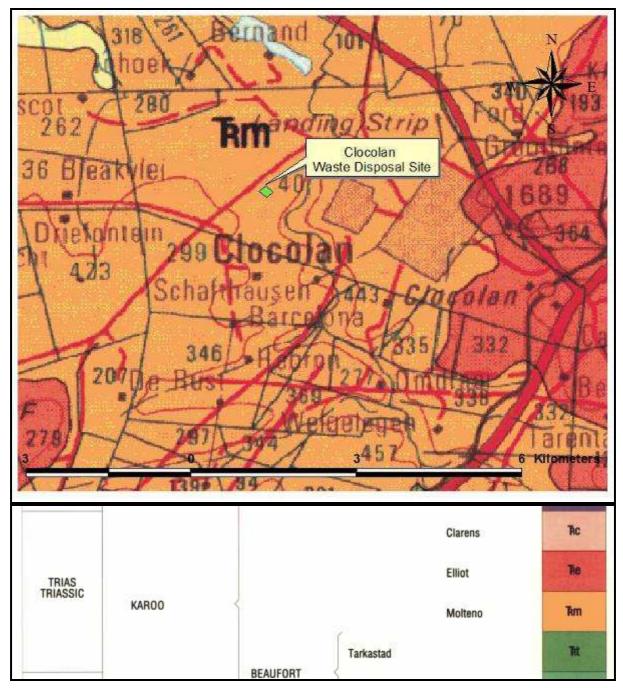

Figure 4.1 The Geology (Geo Map 2826- Windburg) of the Clocolan Waste Site Development

5. PALAEONTOLOGY OF THE AREA

5.1. The Molteno Formation

The Triassic Molteno Formation can have a moderate to high potential for plant fossils from the *Dicroidium* assemblage (Johnson et al, 2006). The *Dicroidium* assemblage is an extinct genus of fork-leaved seed ferns that were distributed over Gondwanaland during the Triassic Period.

Invertebrate fossils are restricted to trace fossils.

6. PALAEONTOLOGICAL SIGNIFICANCE AND RATING

The predicted palaeontological impact of the development is based on the initial mapping assessment and literature reviews as well as information gathered during the field investigation.

The palaeontological significance and rating is summarised in Table 7.1 and 7.2. For the methodology and definitions of impact rating and significance see Appendix A (CES 2011).

| Geological Unit | Rock Type and Age | Fossil Heritage | Vertebrate Biozone | Palaeontological Sensitivity |
|----------------------|---|--|-----------------------|---------------------------------|
| Molteno Formation | Fluvial, braided river sandstone and mudstone TRIASSIC | Plant fossils such as <i>Dicroidium</i> assemblages Invertebrate fossils are restricted to trace fossils. | None | High sensitivity |

 Table 6.1
 Palaeontological Significance of Geological Units on Site

| Table 6.2 | Significance Rating Table as Per CES Template |
|-----------|---|
|-----------|---|

| Rock Unit | Temporal Scale | Spatial Scale (area in which | Degree of confidence (confidence with which | (severity of ne or how bene | severity gative impacts, ficial positive would be) | Overall Sig (The combinat other criteria signific | ion of all the as an overall |
|----------------------|-------------------------|---------------------------------|---|--------------------------------|---|--|---------------------------------|
| NOCK ONIC | (duration of impact) | impact will have an effect) | one has predicted the significance of an impact) | With mitigation | Without mitigation | With mitigation | Without mitigation |
| Molteno Formation | permanent | international | unsure | beneficial | severe | beneficial | Negative |

There is a possibility that tree fossils could be encountered during excavation of bedrock within the development footprint and these fossils would be of low significance. If effective mitigation measures are in place at the time of exposure, and the fossils are successfully excavated for study, this would represent a beneficial palaeontological impact.

7. PALAEONTOLOGICAL IMPACT AND MITIGATION

The predicted palaeontological impact of the development is based on the initial mapping assessment and literature reviews.

The Molteno Formation consists mainly of coarse-grained sandstone with thin layers of interbedded mudstone. The excavation of the underlying bedrock will have the potential to uncover the mud rock and sandstone of the Molteno Formation. Therefore, monitoring and mitigation in terms of the palaeontological heritage are required if the bedrock is exposed.

The following colour coding method was developed to classify a development area's palaeontological impact as illustrated in Figure 7.1:

- Red colouration indicates a very high possibility of finding fossils of a specific assemblage zone. Fossils will most probably be present in all outcrops on the site/route and the chances of finding fossils during the construction phase are very high.
- Orange colouration indicates a possibility of finding fossils of a specific assemblage zone either in outcrops or in bedrock on the site/route.
- Green colouration indicates that there is limit/no possibility of finding fossils in that section of the site/route development.

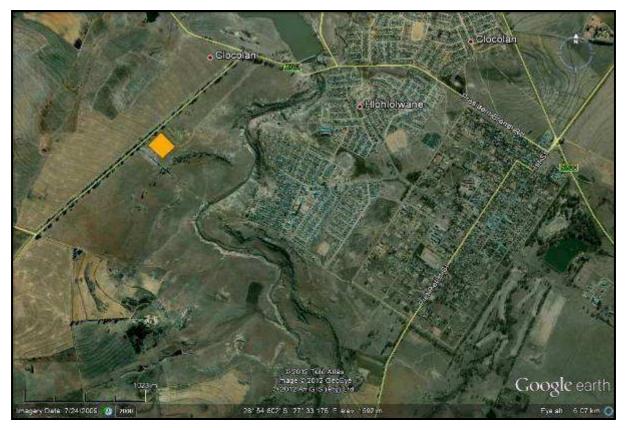

Figure 7.1 Palaeontological Impact of the Proposed Clocolan Waste Disposal Facility

The proposed development involves the excavation of waste disposal cells and infrastructure such as roads and buildings. The construction phase will require excavation of bedrock and has the potential to impact directly on fossil heritage if the Molteno mudstone and sandstone are exposed. From Figure 7.1 the following mitigation measures are recommended:

| Colour Coding (Figure 7.1) | Mitigation Recommended | |
|----------------------------|--|--|
| | The resident ECO must be trained by a professional palaeontologist in | |
| | the recognition of fossils. If fossil material is later discovered it must | |
| | be appropriately protected and the discovery reported to a | |
| Orange Site | palaeontologist for the removal thereof as per SAHRA legislation. All | |
| | earth-moving activities within the bedrock are to be monitored by the | |
| | ECO under guidance of a palaeontologist. A monitoring report should | |
| | be submitted to SAHRA after completion of the earth-moving activity. | |

| Table 7.1 | Site Specific Mitigation Measures |
|-----------|-----------------------------------|
|-----------|-----------------------------------|

8. CONCLUSION

The proposed development site is underlain by the Triassic Molteno Formation that consists of coarse-grained grey sandstone and dark grey mudstone. Soils are derived from the underlying rock and are generally deep and relatively high in fertility.

The development site for the Clocolan Solid Waste Disposal Facility is underlain by the Triassic Molteno Formation. Deep soils are expected over the entire development site. There is a moderate potential for fossil material in the underlying mudstones that may be uncovered during excavations.

Through adequate monitoring and mitigation measures during excavations in the underlying bedrock the impact severity can be lowered to beneficial. The exposure and subsequent reporting of fossils (that would otherwise have remained undiscovered) to a qualified palaeontologist for excavation will have a beneficial palaeontological impact.

It is recommended that:

- The resident ECO must also be trained by a professional palaeontologist in the recognition of fossils. If fossil material is later discovered it must be appropriately protected and the discovery reported to a palaeontologist for the removal thereof as per SAHRA legislation.
- All earth-moving activities within the underlying bedrock with potential impact are to be monitored by a palaeontologist. A monitoring report should be submitted to SAHRA after completion of the earth-moving activities.

10. QUALIFICATIONS AND EXPERIENCE OF THE AUTHOR

Dr Gideon Groenewald has a PhD in Geology from the Nelson Mandela Metropolitan University (1996) and the National Diploma in Nature Conservation from the University of South Africa (1990). He specialises in research on South African Permian and Triassic sedimentology and macrofossils with an interest in biostratigraphy, and palaeoecological aspects. He has extensive experience in the locating of fossil material in the Karoo Supergroup and has more than 20 years of experience in locating, collecting and curating fossils, including exploration field trips in search of new localities in the southern, western, eastern and north-eastern parts of the country. His publication record includes multiple articles in internationally recognized journals. Dr Groenewald is accredited by the Palaeontological Society of Southern Africa (society member for 25 years).

Declaration of Independence

I, Gideon Groenewald, declare that I am an independent specialist consultant and have no financial, personal or other interest in the proposed development, nor the developers or any of their subsidiaries, apart from fair remuneration for work performed in the delivery of palaeontological heritage assessment services. There are no circumstances that compromise the objectivity of my performing such work.

11. APPENDIX A - METHODOLOGY FOR ASSESSING THE SIGNIFICANCE OF IMPACTS

Although specialists will be given relatively free rein on how they conduct their research and obtain information, they will be required to provide their reports to the EAP in a specific layout and structure, so that a uniform specialist report volume can be produced.

To ensure a direct comparison between various specialist studies, a standard rating scale has been defined and will be used to assess and quantify the identified impacts. This is necessary since impacts have a number of parameters that need to be assessed. Four factors need to be considered when assessing the significance of impacts, namely:

- 1. Relationship of the impact to **temporal** scales the temporal scale defines the significance of the impact at various time scales, as an indication of the duration of the impact.
- 2. Relationship of the impact to **spatial** scales the spatial scale defines the physical extent of the impact.
- 3. The severity of the impact the **severity/beneficial** scale is used in order to scientifically evaluate how severe negative impacts would be, or how beneficial positive impacts would be on a particular affected system (for ecological impacts) or a particular affected party.

The severity of impacts can be evaluated with and without mitigation in order to demonstrate how serious the impact is when nothing is done about it. The word 'mitigation' means not just 'compensation', but also the ideas of containment and remedy. For beneficial impacts, optimization means anything that can enhance the benefits. However, mitigation or optimization must be practical, technically feasible and economically viable.

4. The **likelihood** of the impact occurs - the likelihood of impacts taking place as a result of project actions differs between potential impacts. There is no doubt that some impacts would occur (e.g. loss of vegetation), but other impacts are not as likely to occur (e.g. vehicle accident), and may or may not result from the proposed development. Although some impacts may have a severe effect, the likelihood of them occurring may affect their overall significance.

The *environmental significance* scale is an attempt to evaluate the importance of a particular impact. This evaluation needs to be undertaken in the relevant context, as an impact can either be ecological or social, or both. The evaluation of the significance of an impact relies heavily on the values of the person making the judgment. For this reason, impacts of especially a social nature need to reflect the values of the affected society.

Negative impacts that are ranked as being of "VERY HIGH" and "HIGH" significance will be investigated further to determine how the impact can be minimised or what alternative activities or mitigation measures can be implemented. These impacts may also assist decision makers i.e. lots of HIGH negative impacts may bring about a negative decision.

For impacts identified as having a negative impact of "**MODERATE**" significance, it is standard practice to investigate alternate activities and/or mitigation measures. The most effective and practical mitigations measures will then be proposed.

For impacts ranked as "LOW" significance, no investigations or alternatives will be considered. Possible management measures will be investigated to ensure that the impacts remain of low significance.

Table 9-1: Criterion used to rate the significance of an impact

| Significance Rating Table | | | | |
|---|--|--|--|--|
| Temporal Scale (The duration of the impact) | | | | |
| Short term | Less than 5 years (Many construction phase impacts are of a short duration) | | | |
| Medium term | Between 5 and 20 years | | | |
| Long term | Between 20 and 40 years (From a human perspective almost permanent). | | | |
| Permanent | Over 40 years or resulting in a permanent and lasting change that will always be there | | | |
| | Spatial Scale (The area in which any impact will have an affect) | | | |
| Individual | Impacts affect an individual. | | | |
| Localised | Impacts affect a small area, often only a portion of the project area. | | | |
| Project Level | Impacts affect the entire project area. | | | |
| Surrounding Areas | Impacts that affect the area surrounding the development | | | |
| Municipal | Impacts affect either the Local Municipality, or any towns within them. | | | |
| Regional | Impacts affect the wider district municipality or the province as a whole. | | | |
| National | Impacts affect the entire country. | | | |
| International/Global | Impacts affect other countries or have a global influence. | | | |
| Will definitely occur | Impacts will definitely occur. | | | |
| Degree of Conf | idence or Certainty (The confidence to predicted the significance of an impact) | | | |
| Definite | More than 90% sure of a particular fact. Should have substantial supportive data. | | | |
| Probable | Over 70% sure of a particular fact, or of the likelihood of that impact occurring. | | | |
| Possible | Only over 40% sure of a particular fact or of the likelihood of an impact occurring. | | | |
| Unsure | Less than 40% sure of a particular fact or of the likelihood of an impact occurring. | | | |

Table 9-2: The severity rating scale
